Abstract

This paper relates the Defeasible Logic Programming (DeLP) framework and its semantics \( \text{SEM}_{\text{DeLP}} \) to classical logic programming frameworks. In DeLP we distinguish between two different sorts of rules: strict and defeasible rules. Negative literals (\( \sim A \)) in these rules are considered to represent classical negation. In contrast to this, in normal logic programming (NLP), there is only one kind of rules, but the meaning of negative literals (\( \text{not} \ A \)) is different: they represent a kind of negation as failure, and thereby introduce defeasibility. Various semantics have been defined for NLP, notably the well-founded semantics (WFS) in [VGRS88,vRS91] and the stable semantics Stable in [GL88,GL91].

In this paper we consider the transformation properties for NLP introduced by Brass and Dix and suitably adjusted for the DeLP framework. We show which transformation properties are satisfied, thereby identifying aspects in which NLP and DeLP differ. We contend that the transformation rules presented in this paper

Preprint submitted to Elsevier Preprint 2 October 2001
can help to gain a better understanding of the relationship of DeLP semantics with respect to more traditional logic programming approaches. As a byproduct, we get that DeLP is a proper extension of NLP.

KEYWORDS: defeasible argumentation; knowledge representation; logic programming; non-monotonic reasoning.

1 Introduction and motivations

Defeasible Logic Programming (DeLP) [SL92,Gar97,GSC98] is a logic programming formalism which relies upon defeasible argumentation [PV01,CML00] for solving queries. DeLP combines strict rules, defined as in extended logic programming, and defeasible rules, of the form \( A \rightarrow < B \), indicating that reasons to believe in the antecedent \( B \) provide reasons to believe in the consequent \( A \). Solving a query \( Q \) in DeLP gives rise to a proof \( A \) for \( Q \) (written \( \langle A,Q \rangle \) for short) involving both strict and defeasible rules, called argument. In order to determine whether \( Q \) is ultimately accepted as justified belief, a recursive analysis is performed which involves finding defeaters, i.e., arguments against accepting \( A \), which are better than \( A \) (according to a preference criterion). Since defeaters are arguments, a recursive procedure is to be carried out, in which defeaters, defeaters of defeaters, and so on, must be taken into account.

Logic programming has experienced considerable growth in the last decade, and several extensions have been developed and studied, such as normal logic programming (NLP) and extended logic programming (ENLP). For these formalizations different semantics have been developed, such as well-founded semantics and stable model semantics: we refer to [DPP97,BD02,DFN01] for an in-depth discussion of extensions of logic programming and their semantics. In contrast, DeLP has an “operational” semantics which is determined by the outcome of the dialectical process used for answering queries.

In [BD97,BD98,BD99], a number of transformation rules were introduced which allow to “simplify” a normal logic program (nlp) \( P \) to get its well-founded semantics WFS. The application of these rules leads to a new, simplified NLP \( P' \) from which its WFS can be easily read off. In this paper we will focus on finding similar transformation rules for DeLP, which can be used to simplify the knowledge encoded in a DeLP program. In our analysis, we

* This paper emerged while the first author was visiting the University of Koblenz in February 2000. It is part of the joint Argentine-German collaboration project DeReLoP [DSSF99]. A preliminary version appeared at CACIC ’2000 [CDSS00].
show that in DeLP a complete simplification of the original program cannot be achieved. However, our results suggest some connections between the semantics of classical approaches and logic programming with DeLP.

The paper is structured as follows: Section 2 introduces preliminary notions concerning NLP and DeLP. Section 3 introduces transformations for NLP. Section 4 shows how to adapt these transformations for DeLP, analyzing two classes of DeLP programs: DeLP$_{neg}$ (Subsection 4.1) and DeLP$_{not}$ (Subsection 4.2). Subsection 4.4 summarizes the relationships between NLP and DeLP, and the main results we have obtained. Finally, Section 5 discusses related work and concludes.

2 Preliminaries

In order to render the paper in a self-contained manner, this section contains all the necessary definitions. Subsection 2.1 introduces normal logic programs, and Subsection 2.2 introduces the defeasible logic programming framework. We will focus our analysis on propositional logic programs because, following [GL88,Lif94], program rules with variables can be viewed as “schemata” that represent their ground instances. Although there now exist powerful grounding techniques applied by various implementations (smodels, DLV) we believe that handlind programs with free variables and computing appropriate substitutions (variable bindings) can often improve the performance of the system. Therefore, whenever suitable, we are also using the formalism of most general unifiers (mgU) stemming from logic programming.

2.1 Normal Logic Programs (NLP)

**Definition 1 (Normal logic program P)** A normal logic program (nlp) P is a finite set of normal program rules. A normal program rule has the form $A \leftarrow L_1, \ldots, L_k$, where $A$ is an atom and each $L_i$ is an atom $B$ or its negation $\text{not } B$. If $B = \{L_1, \ldots, L_k\}$ is the body of a rule $A \leftarrow B$, we also use the notation $A \leftarrow B^+, \text{not } B^-$, where $B^+$ (resp. $B^-$) contains all the positive (resp. negative) body atoms in $B$.

In NLP, atoms $A$ and negated atoms $\text{not } A$ are called literals. However, we must not confuse this notion with the notion of a literal introduced in Section 2.2. In the sequel we will speak of an atom and its negation, referring to an atom $A$ and its default negation $\text{not } A$. If $B^+ = B^- = \emptyset$, we say that the rule is a fact and denote it by $A \leftarrow \ldots \leftarrow$ (or just by $A$).
We will now introduce some concepts useful for describing what a semantics of a nlp is. Let \( \text{Prog}_L \) be the set of all normal propositional programs with atoms from a signature \( L \). By \( L_P \) we understand the signature of \( P \), i.e. the set of atoms that occur in \( P \). A (partial) interpretation based on a signature \( L \) is a disjoint pair of sets \( I_1, I_2 \) such that \( I_1 \cup I_2 \subseteq L \). A partial interpretation is total if \( I_1 \cup I_2 = L \). We may also view an interpretation \( \langle I_1, I_2 \rangle \) as the set of atoms and negated atoms \( I_1 \cup \text{not} \ I_2 \).

**Definition 2 (Semantics SEM)** A semantics \( \text{SEM} \) is a mapping which assigns to each logic program \( P \) a set \( \text{SEM}(P) \) of (partial) models of \( P \), such that \( \text{SEM} \) is “instantiation invariant”, i.e. \( \text{SEM}(P) = \text{SEM}(\text{ground}(P)) \), where \( \text{ground}(P) \) denotes the Herbrand instantiation of \( P \). A semantics \( \text{SEM} \) is called 3-value based if for each program \( P \) the partial interpretation \( \text{SEM}(P) \) is a 3-valued model \(^1 \) of \( P \).

In Section 3 we will consider a particular 3-valued semantics for the class NLP called the wellfounded semantics WFS, which can be computed by applying transformation rules on a nlp \( P \).

### 2.2 Defeasible Logic Programs (DeLP)

The DeLP language [SL92,Gar97,GSC98] is defined in terms of two disjoint sets of rules: a set of strict rules for representing strict (sound) knowledge, and a set of defeasible rules for representing tentative information. Rules will be defined using literals. A literal \( L \) is an atom \( p \) or a negated atom \( \neg p \), where the symbol \( \neg \) is called strong negation. In addition, we will consider default negation with “not” here. We define formally:

**Definition 3 (Literal, assumption literal)** A literal \( L \) is an atom \( p \) or a negated atom \( \neg p \), where the symbol \( \neg \) represents strong negation. An assumption literal \( A \) has the form “not \( A \)”, where \( A \) is a literal.

**Definition 4 (Strict rules Head \( \leftarrow \) Body)** A strict rule is an ordered pair, conveniently denoted as \( \text{Head} \leftarrow \text{Body} \), the first member of which, Head, is a literal, and the second member, Body, is a finite set of literals, which may be (additionally) negated with “not” (default negation). A strict rule with the head \( L_0 \) and body \( \{L_1, \ldots, L_k\} \) can also be written as \( L_0 \leftarrow L_1, \ldots, L_k \). If the body is empty, it is written \( L \leftarrow \text{true} \), and it is called a fact. Facts may also be written as \( L \).

**Definition 5 (Defeasible rules Head \( \leftarrow\!\!\rightarrow \) Body)** A defeasible rule is an

\(^1 \) We equip \( \leftarrow \) with the Kleene interpretation, where \( \text{undef} \leftarrow \text{undef} \) is considered to be true.
ordered pair, conveniently denoted as Head \( \rightarrow \) Body, the first member of which, Head, is a literal, and the second member, Body, is a finite set of literals, which may be (additionally) negated with “not”. A defeasible rule with the head \( L_0 \) and body \( \{L_1, \ldots, L_k\} \) can also be written as \( L_0 \leftarrow L_1, \ldots, L_k, k > 0 \).

Syntactically, the symbol “\( \leftarrow \) ” is all that distinguishes a defeasible rule from a strict rule. Defeasible rules account for tentative information that can be used if nothing can be argued against it, whereas strict rules are used to represent non-defeasible information.

In the sequel, atoms will be denoted with lowercase letters \( (a, b, \ldots) \). The letter \( r \) (possibly indexed) will be used for denoting rule names. Literals will be denoted with capital letters \( (A, B, \ldots) \), possibly indexed. Sets of atoms will be denoted as \( A, B, \ldots \), possibly indexed. Logic programs will be usually denoted as \( P_1, P_2, \) etc.

**Definition 6 (Defeasible logic program \( \mathcal{P} = (\Pi, \Delta) \))** A defeasible logic program (dlp) is a finite set of strict and defeasible rules. If \( \mathcal{P} \) is a dlp, we will distinguish in \( \mathcal{P} \) the subset \( \Pi \) of strict rules, and the subset \( \Delta \) of defeasible rules. When required, we will denote \( \mathcal{P} \) as \( (\Pi, \Delta) \).

We will distinguish the class of all defeasible logic programs that use only strict (resp. default) negation, denoting them as \( \text{DeLP}_{\text{neg}} \) (resp. \( \text{DeLP}_{\text{not}} \)). Note that strong negation “\( \sim \)” is applied to atoms (also in rule heads), whereas default negation is applied to literals (possibly strongly negated). But default negation does not occur in heads of programs (see Definition 1). We will associate with every program \( \mathcal{P} \) a set of assumable facts of the form \text{assume} \( L \), for every literal \( L \) in \( \mathcal{P} \). Those literals will be given a special meaning in the argumentation framework. They will be used to define the semantics of default negation.

We will write \( \overline{P} \) to denote the complement of a literal \( P \), defined as follows: \( \overline{P} =_{\text{def}} \sim P \), \( \sim P =_{\text{def}} \overline{P} \), and assume \( \overline{P} =_{\text{def}} P \).

Next we will define the notion of a defeasible derivation for a dlp. In brief, it is a finite set of rules obtained by backward chaining from a literal \( Q \) as in a PROLOG program, using both strict and defeasible rules from the given dlp \( \mathcal{P} \). The symbol “\( \sim \)” is considered as part of the predicate when generating a defeasible derivation. The definition is similar to the one of SLDNF-derivation in [Lio87], except that literals negated with “\textit{not}” are associated with assumable facts.

**Definition 7 (Derivation sequence)** A defeasible derivation for a literal \( Q \) in a general dlp \( \mathcal{P} \) (possibly containing assumable facts) is a finite sequence of (instantiations of) rules in \( \mathcal{P} \). For this, we consider sequences \( G_i \) of goals i.e., sequences of sequences of literals, and \( r_i \) of rules for \( i \geq 0 \) as follows:
(1) \( G_0 = [Q] , r_0 \) is not defined.
(2) Let \( G_i = [Q_1, \ldots, Q_m, \ldots, Q_n] \) with \( 1 \leq m \leq n \).
- If there is a strict or defeasible rule in \( \mathcal{P} \) with head \( L_0 \) and body \( \{L_1, \ldots, L_k\} \) such that \( L_0 \) and \( Q_m \) have the most general unifier \( \sigma \), then \( G_{i+1} = [Q_1, \ldots, Q_{m-1}, L_1, \ldots, L_k, Q_{m+1}, \ldots, Q_n] \sigma \) and \( r_{i+1} = (L_0 \leftarrow L_1, \ldots, L_k) \sigma \) or \( r_{i+1} = (L_0 \leftarrow L_1, \ldots, L_k) \sigma \), respectively.
- If \( Q_m \) has the form not \( L \) for some literal \( L \) (possibly negated with \( \sim \)) and the assumable fact \( r = \text{assume } \overline{T} \) is in \( \mathcal{P} \), then \( G_{i+1} = [Q_1, \ldots, Q_{m-1}, Q_{m+1}, \ldots, Q_n] \) and \( r_{i+1} = r \).

The sequence of rules \( S = [r_1, \ldots, r_l] \) (for some suitable \( l > 0 \)) is called defeasible derivation for \( Q \) in \( \mathcal{P} \) if the corresponding sequence \( G_i \) is empty. We say that \( Q \) can be defeasibly derived from \( \mathcal{P} \) and write \( \mathcal{P} \vdash Q \) in this case.

**Definition 8 (Contradictory set of rules)** A set of rules \( S \) is contradictory if there is a defeasible derivation from \( S \) for some literal \( P \) and its complement \( \overline{S} \), i.e., \( S \vdash P \) and \( S \vdash \overline{P} \).

Given a dlp \( \mathcal{P} \), we will always assume that the set \( \Pi \) of strict rules is non-contradictory (i.e., there is no literal \( P \) such that \( \Pi \vdash P \) and \( \Pi \vdash \sim P \)). If a contradictory set of strict rules were used in a dlp, the same problems as in extended logic programming would appear. The corresponding analysis has been done elsewhere [GL90].

**Example 9** Consider an engine the performance of which is determined by two switches sw1 and sw2. The switches regulate different features of the engine’s behavior, such as pumping system and working speed. We can model the engine behavior using a dlp program (\( \Pi, \Delta \)), where

\[
\Pi = \{ (sw1 \leftarrow ), (sw2 \leftarrow ), (heat \leftarrow ), (\sim fuel\_ok \leftarrow pump\_clogged) \}
\]

(specifying that the two switches are on, there is heat, and whenever the pump gets clogged, fuel is not ok), and \( \Delta \) models the possible behavior of the engine under different conditions (Figure 1).

Next we introduce the definition of argument in DeLP. Basically, an argument for a literal \( Q \) is a defeasible derivation \( S = [r_1, \ldots, r_k] \) which is non-contradictory with respect to a given dlp program, and the defeasible information in \( S \) is minimal with respect to set inclusion.

**Definition 10 (Argument)** Given a dlp \( \mathcal{P} = (\Pi, \Delta) \), we will define \( \mathcal{H}\mathcal{B}_{\text{ass}} = \{ \text{assume } L \mid L \text{ is a literal in } \mathcal{P} \} \). An argument \( \mathcal{A} \) for a query \( Q \), denoted \( \langle \mathcal{A}, Q \rangle \), is defined as \( \mathcal{R}_{\mathcal{A}} \cup \mathcal{H}_{\mathcal{A}} \), where \( \mathcal{R}_{\mathcal{A}} \) is a subset of ground instances of the defeasible rules of \( \mathcal{P} \) and \( \mathcal{H}_{\mathcal{A}} \subseteq \mathcal{H}\mathcal{B}_{\text{ass}} \), such that:

(1) there exists a defeasible derivation for \( Q \) from \( \Pi \cup \mathcal{A} \).
\[pump\_fuel\_ok \leftarrow sw1\]

(when \(sw1\) is on, normally fuel is pumped properly);
\[fuel\_ok \leftarrow pump\_fuel\_ok\]

(when fuel is pumped, normally fuel works ok);
\[pump\_oil\_ok \leftarrow sw2\]

(when \(sw2\) is on, normally oil is pumped);
\[oil\_ok \leftarrow pump\_oil\_ok\]

(when oil is pumped, normally oil works ok);
\[engine\_ok \leftarrow fuel\_ok, oil\_ok\]

(when there is fuel and oil, normally engine works ok);
\[\neg engine\_ok \leftarrow fuel\_ok, oil\_ok, heat\]

(when there is fuel, oil and heat, usually engine is not working ok);
\[pump\_clogged \leftarrow pump\_fuel\_ok, low\_speed\]

(when fuel is pumped and speed is low, there are reasons to believe that the pump is clogged);
\[low\_speed \leftarrow sw2\]

(when \(sw2\) is on, normally speed is low);
\[\neg low\_speed \leftarrow sw2, sw1\]

(when both \(sw2\) and \(sw1\) are on, speed is considered not to be low).

Fig. 1. Set \(\Delta\) (Example 9)

(2) \(\Pi \cup \mathcal{A}\) is non-contradictory, and
(3) \(\mathcal{A}\) is minimal with respect to set inclusion.

An argument \(\langle \mathcal{A}, Q \rangle\) is strict iff \(\mathcal{A} = \emptyset\). An argument \(\langle \mathcal{A}_1, Q_1 \rangle\) is a sub-argument of another argument \(\langle \mathcal{A}_2, Q_2 \rangle\), if \(\mathcal{A}_1 \subseteq \mathcal{A}_2\). Given an argument \(\langle \mathcal{A}, Q \rangle\), we will also write \(\mathcal{H}_{\langle \mathcal{A}, Q \rangle}\) to denote the set of assumption literals in \(\langle \mathcal{A}, Q \rangle\). Next we introduce the auxiliary notion of immediate subargument, which will be used later in the proofs of Propositions 48 and 60.

**Definition 11 (Immediate subarguments)** Let \(\langle \mathcal{A}, H \rangle\) be an argument, such that \(H \leftarrow P_1, \ldots, P_k\) is the last strict rule used in the defeasible derivation of \(H\) from \(\Pi \cup \mathcal{A}\). Clearly, in such a case there exist subsets \(\mathcal{A}_1, \ldots, \mathcal{A}_k\) of \(\mathcal{A}\), which are arguments for \(P_1, \ldots, P_k\). We will call \(\langle \mathcal{A}_1, P_1 \rangle, \ldots, \langle \mathcal{A}_k, P_k \rangle\) immediate subarguments of \(\langle \mathcal{A}, H \rangle\).
Example 12 Consider the dlp program ($\Pi, \Delta$), with

$$\Pi = \{(p \leftarrow q, \neg r), (w \leftarrow q, r), (s \leftarrow )\}$$

$$\Delta = \{(q \leftarrow s), (r \leftarrow s)\}$$

It follows that $A = \{(q \leftarrow s), (r \leftarrow s)\}$ is an argument for $w$, and $B = \{\text{assume } \neg r, (q \leftarrow s)\}$ is an argument for $p$. In the argument $\langle B, p \rangle$ the last strict rule used in the derivation of $p$ is $p \leftarrow q, \neg r$. Then $B' = \{q \leftarrow s\}$ is an argument for $q$, and it is an immediate subargument of $\langle B, p \rangle$. In the argument $\langle A, w \rangle$ the last strict rule used in the derivation of $w$ is $w \leftarrow q, r$. Then $\langle A, q \rangle$ and $\langle A, r \rangle$ are immediate subarguments of $\langle A, w \rangle$.

Example 13 Consider Example 9. Then the set

$$A = \{(\text{pump\_fuel\_ok} \leftarrow sw1), (\text{pump\_oil\_ok} \leftarrow sw2), (\text{fuel\_ok} \leftarrow \text{pump\_fuel\_ok}), (\text{oil\_ok} \leftarrow \text{pump\_oil\_ok}), (\text{engine\_ok} \leftarrow \text{fuel\_ok}, \text{oil\_ok})\}$$

is an argument for $\text{engine\_ok}$. The set

$$B = \{(\text{pump\_fuel\_ok} \leftarrow sw1), (\text{low\_speed} \leftarrow sw2), (\text{pump\_clogged} \leftarrow \text{pump\_fuel\_ok}, \text{low\_speed})\}$$

is an argument for $\neg \text{fuel\_ok}$. The set $C = \{\neg \text{low\_speed} \leftarrow sw2, sw1\}$ is an argument for $\neg \text{low\_speed}$.

Given a dlp program $P$, we will denote by $\text{Args}(P)$ the set of all possible arguments $\langle A, Q \rangle$ that can be built from $P$ wrt. arbitrary queries $Q$. We emphasize that this set consists of pairs $\langle A, Q \rangle$ and not just of arguments $A$ alone. This makes the condition $\text{Args}(P) = \text{Args}(P)'$ much stronger and is important for our Proposition 37 to hold.

The following definition captures the notion of conflict between two arguments.

Definition 14 (Counterargument) An argument $\langle A_1, Q_1 \rangle$ counterargues an argument $\langle A_2, Q_2 \rangle$ at a literal $Q$ iff there is a subargument $\langle A, Q \rangle$ of $\langle A_2, Q_2 \rangle$ such that $\Pi \cup \{Q_1, Q\}$ is contradictory.

Example 15 Consider Example 13. Then $\langle B, \neg \text{fuel\_ok} \rangle$ is a counterargument for $\langle A, \text{engine\_ok} \rangle$, since there is a subargument $A' = \{\text{fuel\_ok} \leftarrow \text{pump\_fuel\_ok}, \text{oil\_ok} \leftarrow \text{pump\_oil\_ok}, \text{engine\_ok} \leftarrow \text{fuel\_ok}, \text{oil\_ok}\}$ for $\text{fuel\_ok}$, such that $\Pi \cup \{\text{fuel\_ok}, \neg \text{fuel\_ok}\}$ is contradictory.
Informally, a query $Q$ will succeed if the supporting argument is not defeated; that argument becomes a justification. In order to establish that $A$ is a non-defeated argument, counterarguments that could be *defeaters* for $A$ are considered, i.e., counterarguments that are preferred to $A$ according to some criterion. DeLP considers a particular preference criterion called *specificity* [SL92, GSC98] which favors an argument with greater information content and/or less use of defeasible rules. Next we will introduce this concept formally.

**Definition 16 (Specificity)** Given a dlp program $P$, let $\Pi_G$ denote the set of all rules with nonempty bodies. Let $F$ denote the set of all possible literals that have a defeasible derivation in $P$.

An argument $\langle A_1, Q_1 \rangle$ is strictly more specific than an argument $\langle A_2, Q_2 \rangle$ (denoted $\langle A_1, Q_1 \rangle \succ \langle A_2, Q_2 \rangle$) if and only if:

1. For all $H \subseteq F$ : if $\Pi_G \cup H \cup A_1 \vdash Q_1$ and $\Pi_G \cup H \not\vdash Q_1$, then $\Pi_G \cup H \cup A_2 \not\vdash Q_2$.
2. There exists $H' \subseteq F$ such that $\Pi_G \cup H' \cup A_2 \vdash Q_2$ and $\Pi_G \cup H' \not\vdash Q_2$ and $\Pi_G \cup H' \cup A_1 \not\vdash Q_1$.

**Example 17** Consider the following dlp $P$:

$$P = \{ (p \leftarrow f_1, f_2), (\neg p \leftarrow f_1), (f_1 \leftarrow), (f_2 \leftarrow) \}$$

Then the set of all literals derivable in $P$ is $F = \{ p, \neg p, f_1, f_2 \}$. Consider the arguments $\langle A_1, p \rangle$ and $\langle A_2, \neg p \rangle$, with $A_1 = \{ p \leftarrow f_1, f_2 \}$ and $A_2 = \{ \neg p \leftarrow f_1 \}$. For every $H \subseteq F$, condition 1 in Definition 16 holds. For $H' = \{ f_1 \}$, condition 2 in Definition 16 holds. Hence $\langle A_1, p \rangle$ is strictly more specific than $\langle A_2, \neg p \rangle$.

**Definition 18 (Proper defeater, blocking defeater)** An argument $\langle A_1, Q_1 \rangle$ defeats $\langle A_2, Q_2 \rangle$ at a literal $Q$ iff there exists a subargument $\langle A, Q \rangle$ of $\langle A_2, Q_2 \rangle$ such that $\langle A_1, Q_1 \rangle$ counterargues $\langle A_2, Q_2 \rangle$ at $Q$, and either:

(a) $\langle A_1, Q_1 \rangle$ is strictly more specific than $\langle A, Q \rangle$. In this case $\langle A_1, Q_1 \rangle$ is called a proper defeater of $\langle A, Q \rangle$, or

(b) Neither $\langle A_1, Q_1 \rangle$ is strictly more specific than $\langle A_2, Q_2 \rangle$, nor $\langle A_2, Q_2 \rangle$ is strictly more specific than $\langle A_1, Q_1 \rangle$. In this case $\langle A_1, Q_1 \rangle$ is a blocking defeater of $\langle A, Q \rangle$.

**Example 19** Consider Examples 13 and 15. Then $\langle B, \neg fuel, ok \rangle$ is a proper defeater for $\langle A, engine, ok \rangle$, since it is more specific.

This conceptualization allows us to apply the notion of counterargumentation (Definition 14) and defeat (Definition 18) in a natural way when assumption
Example 20 Consider a dlp \( \mathcal{P} = (\Pi, \Delta) \), where

\[
\Pi = \{ r \leftarrow , s \leftarrow , t \leftarrow , q \leftarrow s \},
\]
\[
\Delta = \{ p \leftarrow \text{not } q, r \leftarrow \}
\]

Then \( \mathcal{A} = \{ p \leftarrow \text{not } q, r \leftarrow \text{assume } \sim q \} \) is an argument for \( p \), which is counterargued by the argument \( \langle \{ q \leftarrow t \}, q \rangle \) as well as by the argument \( \langle \emptyset, q \rangle \).

Since defeaters are arguments, there may exist defeaters for the defeaters and so on. That prompts for a complete dialectical analysis to determine which arguments are ultimately defeated. Ultimately undefeated arguments will be marked as \( U \)-nodes, and the defeated ones as \( D \)-nodes. The formal definitions required for this process are as follows:

**Definition 21 (Argumentation line)**  Let \( \mathcal{P} \) be a dlp, and let \( \langle \mathcal{A}, Q \rangle \) be an argument in \( \mathcal{P} \). An argumentation line starting from \( \langle \mathcal{A}, Q \rangle \), denoted \( \lambda^{\langle \mathcal{A}, Q \rangle} \) (or simply \( \lambda \)) is a possibly infinite sequence of arguments

\[
\lambda^{\langle \mathcal{A}, Q \rangle} = \{ \langle \mathcal{A}_0, Q_0 \rangle, \langle \mathcal{A}_1, Q_1 \rangle, \langle \mathcal{A}_2, Q_2 \rangle, \ldots, \langle \mathcal{A}_n, Q_n \rangle \ldots \}
\]

satisfying the following conditions:

1. If \( \langle \mathcal{A}, Q \rangle \) has no defeaters, then \( \lambda^{\langle \mathcal{A}, Q \rangle} = \{ \langle \mathcal{A}, Q \rangle \} \).
2. If \( \langle \mathcal{A}, Q \rangle \) has a defeater \( \langle \mathcal{B}, S \rangle \) in \( \mathcal{P} \), then \( \lambda^{\langle \mathcal{A}, Q \rangle} = \langle \mathcal{A}, Q \rangle \circ \lambda^{\langle \mathcal{B}, S \rangle} \).

We distinguish two sets in any argumentation line \( \lambda \): the set of supporting arguments \( \lambda_S = \{ \langle \mathcal{A}_0, Q_0 \rangle, \langle \mathcal{A}_2, Q_2 \rangle, \langle \mathcal{A}_4, Q_4 \rangle, \ldots \} \) and the set of interferring arguments \( \lambda_I = \{ \langle \mathcal{A}_1, Q_1 \rangle, \langle \mathcal{A}_3, Q_3 \rangle, \langle \mathcal{A}_5, Q_5 \rangle, \ldots \} \).

Argumentation lines can be thought of as an exchange of arguments between two parties, a proponent and an opponent [Res77]. Dialectics imposes additional requirements on such an argument exchange to be considered rationally acceptable. In such a setting, fallacious reasoning (such as circular argumentation and falling into self-contradiction) is to be avoided. This can be done by requiring that all argumentation lines be acceptable [SCG94]. An acceptable argumentation line starting with an argument \( \langle \mathcal{A}_0, Q_0 \rangle \) constitutes an exchange of arguments which can be pursued until no more arguments can be introduced because of the dialectical constraints discussed above. These notions will be introduced in the following definitions.

**Definition 22 (Contradictory set of arguments)** Given a dlp \( \mathcal{P} = (\Pi, \Delta) \), a set of arguments \( \hat{S} = \bigcup_{i=1}^{n} \{ \langle \mathcal{A}_i, Q_i \rangle \} \) is contradictory wrt \( \mathcal{P} \) iff \( \Pi \cup \bigcup_{i=1}^{n} \mathcal{A}_i \) is contradictory.
Definition 23 (Acceptable argumentation line) Let $\mathcal{P}$ be a dlp, and let
$\lambda = [\langle A_0, Q_0 \rangle, \langle A_1, Q_1 \rangle, \ldots, \langle A_n, Q_n \rangle, \ldots]$ be an argumentation line in $\mathcal{P}$.
Let $\lambda' = [\langle A_0, Q_0 \rangle, \langle A_1, Q_1 \rangle, \ldots, \langle A_k, Q_k \rangle, \ldots]$ be an initial segment of $\lambda$.
The sequence $\lambda'$ is an acceptable argumentation line in $\mathcal{P}$ iff it is the longest initial segment in $\lambda$
satisfying the following conditions:

1. The sets $\lambda'_i$ and $\lambda'_j$ are each non-contradictory sets of arguments wrt $\mathcal{P}$.
2. No argument $\langle A_j, Q_j \rangle$ in $\lambda'$ is a sub-argument of an earlier argument $\langle A_i, Q_i \rangle$ of $\lambda'$ ($i < j$).
3. There is no subsequence of arguments $[\langle A_{i-1}, Q_{i-1} \rangle, \langle A_i, Q_i \rangle, \langle A_{i+1}, Q_{i+1} \rangle]$ in $\lambda'$, such that $\langle A_i, Q_i \rangle$, is a blocking defeater for $\langle A_{i-1}, Q_{i-1} \rangle$ and $\langle A_{i+1}, Q_{i+1} \rangle$ is a blocking defeater for $\langle A_i, Q_i \rangle$.

The rationale for the conditions in Definition 23 can be better understood in a
dialectical setting [SCG94]. Condition 1 disallows the use of contradictory
information on either side (proponent or opponent). Condition 2 eliminates the
"circulus in demonstrando" fallacy (circular reasoning). Finally, condition 3
enforces the use of a stronger argument to defeat an argument which acts as
a blocking defeater.

Example 24 Consider Example 9. The sequence

$$\lambda_1 = [\langle A, \text{engine} \_ \text{ok} \rangle, \langle B, \neg \text{fuel} \_ \text{ok} \rangle, \langle C, \neg \text{low} \_ \text{speed} \rangle]$$

is an acceptable argumentation line, whereas any sequence having the initial
segment

$$\lambda_2 = [\langle A, \text{engine} \_ \text{ok} \rangle, \langle B, \neg \text{fuel} \_ \text{ok} \rangle, \langle D, \text{fuel} \_ \text{ok} \rangle]$$

with $D = \{ \text{pump} \_ \text{fuel} \_ \text{ok} \leftarrow \text{sw1}, \text{fuel} \_ \text{ok} \leftarrow \text{pump} \_ \text{fuel} \_ \text{ok} \}$ is an
argumentation line which is not acceptable, since the last argument defeats $\langle B, \neg \text{fuel} \_ \text{ok} \rangle$, but it is a subargument of a previous argument in $\lambda_2$ (viz. $\langle A, \text{engine} \_ \text{ok} \rangle$).
Hence $\langle D, \text{fuel} \_ \text{ok} \rangle$ is deemed as a fallacious argument to be
excluded from the dialectical analysis.

Proposition 25 Any acceptable argumentation line in a dlp $\mathcal{P}$ is finite.

PROOF. Since $\mathcal{P}$ has no function symbols, and $\mathcal{P}$ is a finite set of program
rules, the set of all possible arguments $\text{Args}(\mathcal{P})$ is necessarily finite. Hence the
only way to get an infinite argumentation line $\lambda = [\langle A_0, Q_0 \rangle, \langle A_1, Q_1 \rangle, \langle A_2, Q_2 \rangle, \ldots, \langle A_n, Q_n \rangle, \ldots]$ is by having the same argument twice in $\lambda$, i.e., $\langle A_i, Q_i \rangle = \langle A_j, Q_j \rangle$, and hence $A_i = A_j$. But this cannot be the case in an
acceptable argumentation line because of condition 2 in Definition 23. Therefore
any acceptable argumentation line $\lambda$ is necessarily finite.
Let $\Lambda^Q = \{\lambda_1, \lambda_2, \ldots, \lambda_m\}$ be the set of all acceptable argumentation lines starting with $\langle A_0, Q_0 \rangle$ in a dlp $\mathcal{P}$. A tree structure can be built out of the elements of $\Lambda^Q$, so that every path in the tree corresponds to some $\lambda_i \in \Lambda^Q$. This structure will be called dialectical tree. Formally:

**Definition 26 (Dialectical tree)** Let $\mathcal{P}$ be a dlp, and let $A_0$ be an argument for $Q_0$ in $\mathcal{P}$. A dialectical tree for $\langle A_0, Q_0 \rangle$, denoted $\mathcal{T}_{\langle A_0, Q_0 \rangle}$, is a tree structure defined as follows:

1. The root node of $\mathcal{T}_{\langle A_0, Q_0 \rangle}$ is $\langle A_0, Q_0 \rangle$.
2. $\langle B', H' \rangle$ is an immediate child of $\langle B, H \rangle$ if there exists an acceptable argumentation line $\lambda^Q = [\langle A_0, Q_0 \rangle, \langle A_1, Q_1 \rangle, \ldots, \langle A_n, Q_n \rangle]$ such that there are two elements $\langle A_{i+1}, Q_{i+1} \rangle = \langle B', H' \rangle$ and $\langle A_i, Q_i \rangle = \langle B, H \rangle$, for some $i = 0, \ldots, n-1$.

Clearly, leaves in a dialectical tree correspond to undefeated arguments. Defeat among arguments in a dialectical tree can be propagated from the leaves up to the root, according to the marking procedure given in Definition 27.

**Definition 27 (Marking of the dialectical tree)** Let $\langle A, Q \rangle$ be an argument and $\mathcal{T}_{\langle A, Q \rangle}$ its dialectical tree, then:

1. All the leaves in $\mathcal{T}_{\langle A, Q \rangle}$ are marked as $U$-nodes.
2. Let $\langle B, H \rangle$ be an inner node of $\mathcal{T}_{\langle A, Q \rangle}$. Then $\langle B, H \rangle$ will be a $U$-node iff each child of $\langle B, H \rangle$ is a $D$-node. The node $\langle B, H \rangle$ will be a $D$-node iff it has at least one child marked as $U$-node.

An argument $A$ for a literal $Q$ which turns to be ultimately labeled as undefeated in $\mathcal{T}_{\langle A, Q \rangle}$ is called a justification for $Q$.

**Definition 28 (Justification)** Let $A$ be an argument for a literal $Q$, and let $\mathcal{T}_{\langle A, Q \rangle}$ be its associated acceptable dialectical tree. The argument $A$ for $Q$ will be a justification iff the root of $\mathcal{T}_{\langle A, Q \rangle}$ is a $U$-node.

It can be shown [Gar97] that for any dlp $\mathcal{P}$, strict arguments in $\mathcal{P}$ have no counterarguments, and therefore no defeaters. As a direct consequence of Definitions 26, 27 and 28, it follows that any strict argument $A$ for a literal $Q$ will be a justification for $Q$: similar results hold for other argumentation systems, such as Vreeswijk’s [Vre93] and Prakken and Sator’s [PS97].

**Example 29** Consider Example 9, and assume our main query is engine-ok. An argument $\langle A, \text{engine-ok} \rangle$ can be built, which is defeated by the argument $\langle B, \neg \text{fuel-ok} \rangle$ (as shown in Examples 13, 15 and 19). Hence, the argument $\langle A, \text{engine-ok} \rangle$ will be provisionally rejected, since it is defeated. However, $\langle A, \text{engine-ok} \rangle$ can be reinstated, since there exists a third argument $C = \{ \neg \text{low-speed} \rightleftharpoons sw2, sw1 \}$ for $\neg \text{low-speed}$ which in turn defeats
\[ \langle A, \text{engine.ok} \rangle \]
\[ \langle B, \sim \text{fuel.ok} \rangle \]
\[ \langle D, \sim \text{engine.ok} \rangle \]
\[ \langle C, \sim \text{low_speed} \rangle \]

Fig. 2. Dialectical tree (Example 9)

\[ \langle B, \sim \text{fuel.ok} \rangle. \]

Hence, \( \langle A, \text{engine.ok} \rangle \) comes to be undefeated again, since the argument \( \langle B, \sim \text{fuel.ok} \rangle \) was defeated. But there is another defeater for \( \langle A, \text{engine.ok} \rangle \), the argument \( \langle D, \sim \text{engine.ok} \rangle \), where \( D = \{ \text{pump.fuel.ok} \leftarrow \text{sw1}, \text{pump.oil.ok} \leftarrow \text{sw2}, \text{fuel.ok} \leftarrow \text{pump.fuel.ok}, \text{oil.ok} \leftarrow \text{pump.oil.ok}, \sim \text{engine.ok} \leftarrow \text{fuel.ok, oil.ok, heat} \} \). Hence \( \langle D, \text{engine.ok} \rangle \) is once again provisionally defeated.

Since there are no more arguments to consider, \( \langle A, \text{engine.ok} \rangle \) turns out to be ultimately defeated, so that we can conclude that the argument \( \langle A, \text{engine.ok} \rangle \) is not justified.

Figure 2 shows the resulting dialectical tree, as well as its associated labeling.

A given query \( Q \) can be associated with a particular answer set according to some criterion. Several criteria have been analyzed corresponding to different outcomes in the dialectical process. A possible criterion is specified in the following definition [Gar97]:

**Definition 30 (Answers to a given query \( Q \))** Given a dlp \( \mathcal{P} \), a query \( Q \) can be classified as a positive, negative, undecided or unknown answer as follows:

1. \( Q \) is a positive answer iff there exists a justification \( \langle A, Q \rangle \).
2. \( Q \) is a negative answer iff for each argument \( \langle A, Q \rangle \), in the dialectical tree \( T_{\langle A, Q \rangle} \), there exists at least a proper defeater for \( A \) marked as \( U \).
3. \( Q \) is an undecided answer iff \( Q \) is not justified, and for each argument \( \langle A, Q \rangle \), it is the case that \( T_{\langle A, Q \rangle} \) has at least one blocking defeater marked as \( U \).
4. \( Q \) is an unknown answer iff there is no argument for \( Q \).

Given a dlp \( \mathcal{P} \), we call \( \text{Positive}(\mathcal{P}) \), \( \text{Negative}(\mathcal{P}) \), \( \text{Undefined}(\mathcal{P}) \) and \( \text{Unknown}(\mathcal{P}) \) the sets of positive, negative, undecided and unknown answers, resp.
From the previous definition we can derive a 3-valued semantics \( \text{SEM}_{\text{DelP}}(\mathcal{P}) \) for a \( \text{dlp} \ \mathcal{P} \), classifying literals in \( \mathcal{P} \) as accepted, rejected or undefined as follows:

**Definition 31 (SEM\(_{\text{DelP}}\))**

For any dlp \( \mathcal{P} \), we define \( \text{SEM}_{\text{DelP}}(\mathcal{P}) = \langle \mathcal{P}_{\text{accepted}}, \mathcal{P}_{\text{rejected}}, \mathcal{P}_{\text{undefined}} \rangle \), where

\[
\mathcal{P}_{\text{accepted}} = \{ Q \mid Q \in \text{Justified}(\mathcal{P}) \}
\]

\[
\mathcal{P}_{\text{rejected}} = \{ Q \mid Q \in \text{Unknown}(\mathcal{P}) \cup \text{Negative}(\mathcal{P}) \}
\]

\[
\mathcal{P}_{\text{undefined}} = \{ Q \mid Q \in \text{Undefined}(\mathcal{P}) \}.
\]

**Example 32** Consider \( \mathcal{P} \) as defined in Example 9, and consider the analysis performed in Example 29. Then \( \text{engine\.ok} \in \text{Negative}(\mathcal{P}) \), \( \text{~engine\.ok} \in \text{Positive}(\mathcal{P}) \), \( \text{heat} \in \text{Positive}(\mathcal{P}) \), and \( \text{working\.temperature\.low} \in \text{Unknown}(\mathcal{P}) \). Hence \( \{ \text{~engine\.ok,heat} \} \subseteq \mathcal{P}_{\text{accepted}} \), and \( \text{engine\.ok} \in \mathcal{P}_{\text{rejected}} \).

3 Transformations for NLP: classifying well-founded semantics

We are now considering logic programs containing default negation \( \text{not} \). A program transformation is a relation \( \mapsto \) between ground logic programs [BD97,BD99,BDFZ01]. A semantics SEM allows a transformation \( \mapsto \) iff \( \text{SEM}(\mathcal{P}_1) = \text{SEM}(\mathcal{P}_2) \), for all \( \mathcal{P}_1 \) and \( \mathcal{P}_2 \), such that \( \mathcal{P}_1 \mapsto \mathcal{P}_2 \). In this case we also say that the transformation \( \mapsto \) holds wrt. SEM. Well-founded semantics for NLP can be elegantly characterized by a set of transformation rules [BD99], which reduce a given nlp program \( \mathcal{P} \) into a simplified version \( \mathcal{P}' \), from which the WFS can be easily read off.

**Definition 33 (Transformation rules for WFS)** Given a program \( \mathcal{P} \in \text{Prog}_L \), let \( \text{HEAD}(\mathcal{P}) \) be the set of all head-atoms of \( \mathcal{P} \), i.e., \( \text{HEAD}(\mathcal{P}) = \{ H \mid H \leftarrow B^+, \text{not} B^- \in \mathcal{P} \} \). Let \( \mathcal{P}_1 \) and \( \mathcal{P}_2 \) be ground programs. The following transformation rules characterize WFS:

\( \text{RED}^+ \) (Positive Reduction): Program \( \mathcal{P}_2 \) results from program \( \mathcal{P}_1 \) by \( \text{RED}^+ \) (written \( \mathcal{P}_1 \mapsto_P \mathcal{P}_2 \)) iff there is a rule \( H \leftarrow B \) in \( \mathcal{P}_1 \) and a negative literal \( \text{not} B \in B \) such that there is no rule about \( B \) in \( \mathcal{P}_1 \), i.e., \( B \notin \text{HEAD}(\mathcal{P}_1) \), and \( \mathcal{P}_2 = (\mathcal{P}_1 \setminus \{ H \leftarrow B \}) \cup \{ H \leftarrow (B \setminus \{ \text{not} B \}) \} \).

\( \text{RED}^- \) (Negative Reduction): Program \( \mathcal{P}_2 \) results from program \( \mathcal{P}_1 \) by \( \text{RED}^- \) (written \( \mathcal{P}_1 \mapsto_N \mathcal{P}_2 \)) iff there is a rule \( H \leftarrow B \) in \( \mathcal{P}_1 \) and a negative literal \( \text{not} B \in B \) such that \( B \) appears as a fact in \( \mathcal{P}_1 \), and \( \mathcal{P}_2 = \mathcal{P}_1 \setminus \{ H \leftarrow B \} \).

\( \text{SUB} \) (Deletion of non-minimal rules): Program \( \mathcal{P}_2 \) results from pro-
gram $\mathcal{P}_1$ by $\text{SUB}$ (written $\mathcal{P}_1 \rightarrow_M \mathcal{P}_2$) iff there are rules $H \leftarrow B$ and $H \leftarrow B'$ in $\mathcal{P}_1$ such that $B \subset B'$ and $\mathcal{P}_2 = \mathcal{P}_1 \setminus \{H \leftarrow B\}$.

**UNFOLD (Unfolding):** Program $\mathcal{P}_2$ results from program $\mathcal{P}_1$ by $\text{UNFOLD}$ (written $\mathcal{P}_1 \rightarrow_U \mathcal{P}_2$) iff there is a rule $H \leftarrow B$ in $\mathcal{P}_1$ and a positive literal $B \in B$ such that $\mathcal{P}_2 = \mathcal{P}_1 \setminus \{H \leftarrow B\} \cup \{H \leftarrow ((B \setminus \{B\}) \cup B') \mid B \leftarrow B' \in \mathcal{P}_1\}$.

**TAUT (Deletion of Tautologies):** Program $\mathcal{P}_2$ results from program $\mathcal{P}_1$ by $\text{TAUT}$ (written $\mathcal{P}_1 \rightarrow_T \mathcal{P}_2$) iff there is $H \leftarrow B \in \mathcal{P}_1$ such that $H \in B$ and $\mathcal{P}_2 = \mathcal{P}_1 \setminus \{H \leftarrow B\}$.

A program $\mathcal{P}'$ is a normal form of a program $\mathcal{P}$ wrt. a transformation “$\rightarrow$” iff $\mathcal{P} \rightarrow^* \mathcal{P}'$, where $\rightarrow^*$ denotes the reflexive-transitive closure of $\rightarrow$, and $\mathcal{P}'$ is irreducible, i.e., there is no program $\mathcal{P}''$ such that $\mathcal{P}' \rightarrow \mathcal{P}''$.

Let “$\rightarrow_R$” be the rewriting system consisting of the above five transformations, i.e., $\rightarrow_R = \rightarrow_T \cup \rightarrow_U \cup \rightarrow_M \cup \rightarrow_P \cup \rightarrow_N$. Two distinctive features of this rewriting system [BD98] are that it is weakly terminating (i.e., each ground program $\mathcal{P}$ has a normal form $\mathcal{P}'$), and confluent (i.e., given a program $\mathcal{P}$, by applying the transformations in any fair order, we eventually arrive at a normalform $\text{norm}_\text{WFS}(\mathcal{P})$). This normalform $\text{norm}_\text{WFS}(\mathcal{P})$ is a residual program, consisting of rules without positive body atoms. For such a simplified program, its well-founded semantics can be easily read off as follows:

**Definition 34 (SEM$_\text{min}$)** We define $\text{SEM}_\text{min}(\mathcal{P}) = \{\mathcal{P}_\text{true}, \mathcal{P}_\text{false}, \mathcal{P}_\text{undef}\}$ for any nlp $\mathcal{P}$, where

- $\mathcal{P}_\text{true} = \{H | H \leftarrow \in \mathcal{P}\}$
- $\mathcal{P}_\text{false} = \{H | H \in \mathcal{L} \setminus \text{HEAD}(\mathcal{P})\}$
- $\mathcal{P}_\text{undef} = \{H | H \in \mathcal{L} \setminus (\mathcal{P}_\text{true} \cup \mathcal{P}_\text{false})\}$

To illustrate our transformations, we consider the following example taken from [DOZ01]:

**Example 35 (Computing WFS)** We consider the program $\mathcal{P}_1$ and reduce it as follows:

\[
\begin{align*}
p \quad & \quad \text{p} \\
q \leftarrow \text{not } p \quad & \quad q \leftarrow \text{not } p \\
q \leftarrow t, \text{not } p \quad & \quad q \leftarrow \text{not } p \\
s \leftarrow \text{not } q \quad & \quad s \leftarrow \text{not } q \\
q \leftarrow r \quad & \quad q \leftarrow r \\
r \leftarrow q \quad & \quad r \leftarrow q
\end{align*}
\]
In the next step, we can apply **UNFOLD** to one of the two last rules to get:

\[
p
\]

\[
s \leftarrow \text{not } q
\]

\[
q \leftarrow q
\]

\[
r \leftarrow q
\]

Now we can delete the resulting tautology by the application of **TAUT** and then use **Red**

\[
p
\]

\[
s \leftarrow \text{not } q \rightarrow_{\text{Red}} s
\]

\[
r \leftarrow q
\]

Finally applying **UNFOLD** to the last one, we get to norm_{WFS}(P_1) :

\[
p
\]

\[
s
\]

Thus, the wellfounded semantics of P_1 is:

\[
WFS(P_1) = \{p, s, \text{not } q, \text{not } t, \text{not } r\}
\]

**Theorem 36 (Classifying WFS [BD99])**

\[
WFS(P) = SEM_{\text{min}}(\text{norm}_{WFS}(P)).
\]

4 Transformation Properties in DeLP

As stated in the introduction, we want to analyze whether transformations for NLP as the ones described above also hold for a DeLP program. Such an analysis is very complicated for the whole class DeLP, where we have not only two sorts of rules, strict and defeasible rules, but also two different kinds of negation, ~ and not. Adapting the transformation rules presented in Section 3 to this class of programs is a nontrivial task. In fact, even defining a semantics for general programs in DeLP is highly nontrivial and subject of ongoing research.

In our analysis, we will therefore focus first on DeLP\textsubscript{neg} (i.e., DeLP with strict negation “\sim”). As the transformations in [BDFZ01,BD98] are defined with respect to a NLP setting, we will adapt them accordingly. Therefore, we extend our previous terminology to be applied to a DeLP\textsubscript{neg} program \( P \).
(thus $\text{HEAD}(\mathcal{P})$ will stand for all heads of rules in $\mathcal{P}$, etc.), distinguishing strict rules from defeasible rules when needed. In Section 4.2 we will consider $\text{DeLP}_\text{nat}$ (i.e., $\text{DeLP}$ with default negation not). In that case, a similar analysis will be performed.

The following propositions provide ways of determining whether two $dlp$ programs have the same semantics. These results will be used in the following sections.

**Proposition 37** Let $\mathcal{P}$ and $\mathcal{P}'$ be two $dlp$ programs. If $\text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P}')$, then $\text{SEM}_{\text{DeLP}}(\mathcal{P}') = \text{SEM}_{\text{DeLP}}(\mathcal{P})$.

**Proof.** This is a direct consequence of the Definition 31, since the semantics of $\text{DeLP}$ is entirely determined by relationships among arguments.

The converse does not hold, as shown in the following example.

**Example 38** Let $\mathcal{P}_1 = \{ p \leftarrow q, p \leftarrow r, q \leftarrow r \}$, and let $\mathcal{P}_2 = \{ p \leftarrow q, q \leftarrow r \}$. Clearly, $\text{SEM}_{\text{DeLP}}(\mathcal{P}_1) = \text{SEM}_{\text{DeLP}}(\mathcal{P}_2)$, since $\{p, q, r\} = \mathcal{P}_1^{\text{accepted}} = \mathcal{P}_2^{\text{accepted}}$. However $\text{Args}(\mathcal{P}_1) \neq \text{Args}(\mathcal{P}_2)$ (since $\langle \{ p \leftarrow r \}, p \rangle$ is an argument in $\mathcal{P}_1$ but not in $\mathcal{P}_2$).

**Definition 39 (Isomorphic dialectical trees)** Given two arguments $\langle A_1, Q_1 \rangle$ and $\langle A_2, Q_2 \rangle$, their associated dialectical trees $\mathcal{T}_{(A_1, Q_1)}$ and $\mathcal{T}_{(A_2, Q_2)}$ will be isomorphic iff

1. $Q_1 = Q_2$, and both $\langle A_1, Q_1 \rangle$ and $\langle A_2, Q_2 \rangle$ have no defeaters, or
2. $\mathcal{T}_{(A_1, Q_1)}$ has $\mathcal{T}_1, \ldots, \mathcal{T}_k$ as immediate subtrees, and $\mathcal{T}_{(A_2, Q_2)}$ has $\mathcal{T}_1', \ldots, \mathcal{T}_k'$ as immediate subtrees, and there exists a one-to-one correspondence $f: \{\mathcal{T}_1, \ldots, \mathcal{T}_k\} \mapsto \{\mathcal{T}_1', \ldots, \mathcal{T}_k'\}$, such that
   a. $\mathcal{T}_i$ and $f(\mathcal{T}_i)$ are isomorphic, $i = 1, \ldots, k$, and
   b. The root of $\mathcal{T}_i$ is a proper (resp. blocking) defeater for $\langle A_1, Q_1 \rangle$ and the root of $f(\mathcal{T}_i)$ is a proper (resp. blocking) defeater for $\langle A_2, Q_2 \rangle$, for $i = 1, \ldots, k$.

**Proposition 40** Let $\mathcal{P}_1$ and $\mathcal{P}_2$ be two $\text{DeLP}_\text{nat}$ programs, such that $\mathcal{T}_{(A_1, Q_1)}$ is the associated dialectical tree for an argument $\langle A_1, Q_1 \rangle$ in $\mathcal{P}_1$, and $\mathcal{T}_{(A_2, Q_2)}$ is the associated dialectical tree for an argument $\langle A_2, Q_2 \rangle$ in $\mathcal{P}_2$. If $\mathcal{T}_{(A_1, Q_1)}$ and $\mathcal{T}_{(A_2, Q_2)}$ are isomorphic, then $Q_1 \in \mathcal{P}_1^{\text{accepted}}$ (resp. $\mathcal{P}_1^{\text{rejected}}$, $\mathcal{P}_1^{\text{undef}}$) iff $Q_2 \in \mathcal{P}_2^{\text{accepted}}$ (resp. $\mathcal{P}_2^{\text{rejected}}$, $\mathcal{P}_2^{\text{undef}}$).

**Proof.** This proposition is direct consequence of the definition of marking of a dialectical tree (Definition 27).
Corollary 41 Let $P_1$ and $P_2$ be two $\text{DeLP}_{\text{not}}$ programs, such that $\text{HEAD}(P_1) = \text{HEAD}(P_2)$. Suppose that for any literal $Q$ in $\text{HEAD}(P_1)$, there exists a dialectical tree $T_{(A,Q)}$ in $P_1$, iff there exists an isomorphic dialectical tree $T_{(B,Q)}$ in $P_2$. Then $\text{SEM}_{\text{DeLP}}(P_1) = \text{SEM}_{\text{DeLP}}(P_1)$.

4.1 Transformation Properties in $\text{DeLP}_{\text{neg}}$

Below we will introduce tentative extensions to $\text{DeLP}_{\text{neg}}$ of the previous transformation rules. The distinguishing features of the transformation rules are discussed next. For each transformation, $P_1$ and $P_2$ denote ground dlp programs. Some transformation rules have special requirements which appear in boldface.

RED$_{\text{neg}}$+: Program $P_2$ will result from program $P_1$ by RED$_{\text{neg}}$+ (written $P_1 \leftrightarrow_{\text{neg}} P_2$) iff there is a rule $H \leftarrow B$ in $P_1$ and a negative literal $\neg B \in B$ such that there is no rule about $B$ in $P_1$, i.e., $B \notin \text{HEAD}(P_1)$, and $P_2 = (P_1 \setminus \{H \leftarrow B\}) \cup \{H \leftarrow (B \setminus \{\neg B\})\}$.

RED$_{\text{neg}}$-: Program $P_2$ will result from program $P_1$ by RED$_{\text{neg}}$- (written $P_1 \leftrightarrow_{\text{neg}} P_2$) iff there is a rule $H \leftarrow B$ in $P_1$ and a negative literal $\neg B \in B$ such that $B$ appears as a fact in $P_1$, and $P_2 = P_1 \setminus \{H \leftarrow B\}$.

SUB$_{\text{neg}}$: Program $P_2$ will result from program $P_1$ by SUB (written $P_1 \leftrightarrow P_2$) iff there are strict rules $H \leftarrow B$ and $H \leftarrow B'$ in $P_1$ such that $B \subseteq B'$ and $P_2 = P_1 \setminus \{H \leftarrow B'\}$. The rule $H \leftarrow B_2$ is called non-minimal rule wrt. $H \leftarrow B_1$.

UNFOLD$_{\text{neg}}$: Suppose program $P_1$ contains a strict rule $H \leftarrow B$ such that there is no defeasible rule in $P_1$ with head $H$.

Then program $P_2$ will result from program $P_1$ by UNFOLD$_{\text{neg}}$ (written $P_1 \leftrightarrow_{\text{neg}} P_2$) iff there is a positive literal $B \in B^2$ which does not appear as head of a defeasible rule in $P_1$, such that $P_2 = P_1 \setminus \{H \leftarrow B\} \cup \{H \leftarrow ((B \setminus \{B\}) \cup B') | B \leftarrow B' \in P_1\}$.

The clause $H \leftarrow B$ is said to be UNFOLD$_{\text{neg}}$-related with each $B \leftarrow B_i \in P_1$ (for $i = 1, \ldots, n$).

TAUT$_{\text{neg}}$: Program $P_2$ will result from program $P_1$ by TAUT$_{\text{neg}}$ (written $P_1 \leftrightarrow_{\text{neg}} P_2$) iff there is $H \leftarrow B \in P_1$ such that $H \in B$ and $P_2 = P_1 \setminus \{H \leftarrow B\}$.

First we consider RED$_{\text{neg}}$+. This transformation rule does not hold for strict negation. Note that whereas RED$_{\text{neg}}$+ captures the idea that not A trivially holds whenever A cannot be derived (and for that reason not A can be deleted), the

\footnote{Note that we do not distinguish between atoms and their negations because negated literals are treated as new predicate names.}
same principle cannot be applied to \( \sim A \), which holds whenever there is a
derivation for \( \sim A \).

**Example 42** Consider the following DeLP\textsubscript{neg} program: \( \Pi = \{ (p \leftarrow \sim s), \)
\( (\sim s \leftarrow t), (q_1 \leftarrow ), (q_2 \leftarrow ) \} \) and \( \Delta = \{ (t \leftarrow q_1), (\sim t \leftarrow q_1, q_2) \} \).
Here \( p \) is not justified from \( \mathcal{P} \) (since the argument \( A_1 = \{ t \leftarrow q_1 \} \) for \( p \)
is defeated by the argument \( A_2 = \{ \sim t \leftarrow q_1, q_2 \} \) for \( \sim t \). If we considered
\( \mathcal{P}' = \text{RED}_{\text{neg}}^\text{+}(\mathcal{P}) \) we would get \( p \) as a fact, so \( p \) would be justified in \( \mathcal{P}' \).

Let us now consider \( \text{RED}_{\text{neg}}^- \). This transformation rule holds for both defeasible and strict rules in a DeLP\textsubscript{neg} program \( \mathcal{P} \), as shown in Proposition 43

**Proposition 43** Let \( \mathcal{P} \) be a DeLP\textsubscript{neg} program. Let \( \mathcal{P}' \) be the resulting program
of applying \( \text{RED}_{\text{neg}}^- \), i.e., \( \mathcal{P} \mapsto_{\text{Mneg}} \mathcal{P}' \). Then \( \text{SEM}_{\text{DeLP}}(\mathcal{P}') = \text{SEM}_{\text{DeLP}}(\mathcal{P}) \).

**PROOF.** Let \( \mathcal{P} \) be a DeLP\textsubscript{neg} program, and let \( (A \leftarrow) \in \mathcal{P} \). Furthermore,
let \( r = P \leftarrow Q_1, ..., Q_n \) (resp. \( P \leftarrow Q_1, ..., Q_n \)) be a rule in \( \mathcal{P} \), such that
\( \sim A \equiv Q_i \), for some \( i \). Then \( r \) cannot be used in any defeasible derivation
corresponding to an argument in \( \mathcal{P} \), since if \( r \) is used, then both \( \sim A \) and
\( A \) follow from \( \Pi \cup A \), contradicting the definition of argument). Then, each
argument that can be built from \( \mathcal{P} \) can also be built from \( \mathcal{P}' = \mathcal{P} \setminus \{ r \} \). Thus
\( \text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P}') \), and therefore \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

Let us now consider \( \text{SUB}_{\text{neg}} \). This transformation holds for strict rules, as
shown in Proposition 45. It does not hold in DeLP\textsubscript{neg} for defeasible rules
(since having more literals in the body gives more specific information), as
shown in Example 44

**Example 44** Let \( \mathcal{P} = (\Pi, \Delta) \), where \( \Pi = \{ q_1, q_2 \} \) and \( \Delta = \{ (p \leftarrow q_1, q_2), \)
\( (p \leftarrow q_1), (\sim p \leftarrow q_2) \} \). The argument \( A = \{ (p \leftarrow q_1, q_2) \} \) for \( p \)
is strictly more specific than \( B = \{ (\sim p \leftarrow q_2) \} \) for \( \sim p \). However, if we
consider \( \mathcal{P}' = \mathcal{P} \setminus \{(p \leftarrow q_1, q_2)\} \), then we get two arguments which block
each other \( (A = \{ (p \leftarrow q_1) \} \) for \( p \) and \( B = \{ (\sim p \leftarrow q_2) \} \) for \( \sim p \)).

**Proposition 45** Let \( \mathcal{P} \) be a DeLP\textsubscript{neg} program. Let \( \mathcal{P}' \) be the program resulting
from applying \( \text{SUB}_{\text{neg}} \), i.e., \( \mathcal{P} \mapsto_{\text{Mneg}} \mathcal{P}' \). Then \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

**PROOF.** Clearly, \( \mathcal{P} = \mathcal{P} \setminus \{ r \mid r \text{ is a non-minimal rule } \} \). Let \( r = P \leftarrow Q_1, ..., Q_k \)
be a non-minimal rule in \( \mathcal{P} \), and assume there is an argument \( A \) for some literal \( H \) in which \( r \) is part of the defeasible derivation for \( H \).
From the definition of defeasible derivation, for each literal \( Q_1, ..., Q_k \) there
is an argument \( \langle B_1, Q_1 \rangle, \ldots, \langle B_k, Q_k \rangle \), such that \( \bigcup_{i=1}^{k} B_i \subseteq A \). Since \( r \) is a
non-minimal rule, there exists \( r' = P \leftarrow Q_1, ..., Q_j \in \Pi, j < k \), such that
for each literal \(Q_i\) \((i = 1, \ldots, j)\) there are arguments \(\langle B_1, Q_1 \rangle, \ldots, \langle B_j, Q_j \rangle\). But \(\bigcup_{i=1}^j B_i \subseteq \bigcup_{k=1}^k B_k\). Hence by replacing \(r\) by \(r'\) we get either the same set \(\mathcal{A}\) as an argument for \(H\), or a proper subset \(\mathcal{A}' \subset \mathcal{A}\) must be an argument for \(H\). This means that \(\mathcal{A}\) is not an argument according to Definition 10, because it does not satisfy condition 3. In any case, the rule \(r\) can be removed from \(\mathcal{P}\), without affecting the arguments that can be obtained from \(\mathcal{P}\). Therefore \(\text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P}')\) (\(\mathcal{P}' = \mathcal{P} \setminus \{r\}\)). Hence \(\text{SEM}_{\text{DelP}}(\mathcal{P}) = \text{SEM}_{\text{DelP}}(\mathcal{P}')\).

Let us now consider \(\text{UNFOLD}_{\text{neg}}\). As indicated in its definition, this property is only defined for a certain class of strict rules. It does not hold for defeasible rules, as shown in Example 46. It does not hold for strict rules in general either: we imposed the additional condition that no defeasible rule has the same head as the literal which is being removed when applying “unfolding”. The reason for doing so is shown in Example 47.

**Example 46 (UNFOLD does not hold for defeasible rules)** Consider the following example

<table>
<thead>
<tr>
<th>(\Pi)</th>
<th>(\Delta)</th>
</tr>
</thead>
<tbody>
<tr>
<td>has_feathers (\leftarrow) flies (\leftarrow) bird</td>
<td></td>
</tr>
<tr>
<td>has_beak (\leftarrow) (\neg)flies (\leftarrow) bird, wounded</td>
<td></td>
</tr>
<tr>
<td>wounded (\leftarrow) bird (\leftarrow) has_feathers, has_beak</td>
<td></td>
</tr>
</tbody>
</table>

In \(\mathcal{P}\), there is an argument \(\mathcal{A}_1 = \{ (\neg\text{flies} \leftarrow \text{bird, wounded}), (\text{bird} \leftarrow \text{has_feathers, has_beak})\} \) for \(\neg\text{flies}\) which is strictly more specific than \(\mathcal{A}_2 = \{ (\text{flies} \leftarrow \text{bird}), (\text{bird} \leftarrow \text{has_feathers, has_beak})\}\) for \(\text{flies}\). In this case, the first argument is a justification. However, if \(\text{UNFOLD}_{\text{neg}}\) is applied to defeasible rules, we get \(\mathcal{P}' = (\Pi, \Delta')\), with \(\Delta' = \{ (\text{flies} \leftarrow \text{has_feathers, has_beak}), (\neg\text{flies} \leftarrow \text{bird, wounded}), (\text{bird} \leftarrow \text{has_feathers, has_beak})\}\). In \(\mathcal{P}'\) we have two conflicting arguments, \(\mathcal{A}_1 = \{ (\neg\text{flies} \leftarrow \text{bird, wounded}), (\text{bird} \leftarrow \text{has_feathers, has_beak})\}\) for \(\neg\text{flies}\) and \(\mathcal{A}_2 = \{ (\text{flies} \leftarrow \text{has_feathers, has_beak})\}\) for \(\text{flies}\). In this case, neither of them is strictly more specific than the other.

**Example 47** Let \(\mathcal{P} = (\Pi, \Delta)\) be a dlp, where \(\Pi = \{ (p \leftarrow q, s), (q \leftarrow f_1), (q \leftarrow f_2), (s \leftarrow \top) \}\) and \(\Delta = \{ q \leftarrow s \}\). If we could apply \(\text{UNFOLD}_{\text{neg}}\) on rule \(p \leftarrow q, s\) w.r.t. the literal \(q\), we would get the program \(\mathcal{P}' = \mathcal{P} \cup \{(p \leftarrow q, s)\} \cup \{(p \leftarrow f_1, s), (p \leftarrow f_2, s)\}\). But \(\mathcal{A}_1 = \{ q \leftarrow s \}\) is an argument for \(p\) in \(\mathcal{P}\), but it does not exist in \(\mathcal{P}'\).

In order to simplify the analysis of \(\text{UNFOLD}_{\text{neg}}\), we will define a special transformation \(\text{UNFOLD}_{\text{neg}}^{r_i}\) corresponding to \(\text{UNFOLD}_{\text{neg}}\) applied to a particular \(\text{UNFOLD}_{\text{neg}}\)-related rule \(r_i\).
Definition 48 (Transformation UNFOLD\textsuperscript{neg}\textsubscript{ri}) Suppose program \(P_1\) contains a strict rule \(H \leftarrow B\) such that there is no defeasible rule in \(P_1\) with head \(H\).

Then program \(P_2\) will result from program \(P_1\) by UNFOLD\textsuperscript{neg}\textsubscript{ri} (written \(P_1 \mapsto \text{UNFOLD}_{neg}^{ri} P_2\)) iff there is a positive literal \(B \in \mathcal{B}\) which does not appear as head of a defeasible rule in \(P_1\), such that \(P_2 = P_1 \setminus \{H \leftarrow B\} \cup \{H \leftarrow ((\mathcal{B} \setminus \{B\}) \cup \mathcal{B}^\prime) \mid r_i = B \leftarrow \mathcal{B}^\prime \in \mathcal{P}_1\}.\) (Such \(r_i\) are called UNFOLD\textsuperscript{neg}\textsubscript{ri} related.)

Proposition 49 Let \(P_1\) be a DeLP\textsuperscript{neg} program which contains a strict rule \(r=H \leftarrow B\), such that \(r_1, r_2, \ldots, r_k\) are all those rules in \(P_1\) that are UNFOLD\textsuperscript{neg}\textsubscript{ri}-related to \(r\). Consider the sequence of programs \(P = P_1 \mapsto \text{UNFOLD}_{neg}^{ri} P_2 \mapsto \text{UNFOLD}_{neg}^{ri} P_3 \mapsto \cdots \mapsto P_k \mapsto P'\). Then \(P \mapsto \text{UNFOLD}_{neg} P'\) wrt rule \(r\).

**Proof.** Direct consequence of Definition 48 and the definition of UNFOLD\textsuperscript{neg}.

We present next a particular property of immediate subarguments in DeLP\textsuperscript{neg}, which will allow us to show that the transformation \(\mapsto \text{UNFOLD}_{neg}^{ri}\) preserves semantics when applied to a given DeLP\textsuperscript{neg} program.

Proposition 50 Let \(\langle A, H \rangle\) be an argument in DeLP\textsuperscript{neg}, such that the last rule used in the derivation is the strict rule \(H \leftarrow P_1, \ldots, P_k\). Then all immediate subarguments \(\langle A_1, P_1 \rangle, \ldots, \langle A_k, P_k \rangle\) are such that \(A_i = A, \forall i = 1, \ldots, k\).

**Proof.** Since \(\langle A, H \rangle\) is an argument, then \(\Pi \cup A \vdash H\), such that there exists a defeasible derivation \(S = [r_1, \ldots, r_k]\) where \(r_1 = H \leftarrow P_1, \ldots, P_k\). Clearly, the sequence \(S' = [r_2, \ldots, r_k]\) provides a defeasible derivation for every element of the sequence of goals \(G=[P_1, \ldots, P_k]\), using the same set \(A\) of defeasible information as in \(S\). In particular, \(\Pi \cup A \vdash P_i, \forall i = 1, \ldots, k\), such that \(A\) is minimal and non-contradictory. Thus \(A\) is an argument for \(P_i, \forall i = 1, \ldots, k\).

Proposition 51 Let \(P_1\) be a DeLP\textsuperscript{neg} program, and let \(P_2\) be the program resulting from applying \(\mapsto \text{UNFOLD}_{neg}^{ri}\) wrt some rule \(r_1\).

Let \(\langle A, H \rangle\) be an argument in \(P_1\) affected by the application of \(\mapsto \text{UNFOLD}_{neg}^{ri}\). Then \(\langle A, H \rangle\) is also an argument in \(P_2\), and \(\text{Args}(P_1) = \text{Args}(P_2)\).

**Proof.** Let \(P_1 = (\Pi, \Delta)\) be a DeLP\textsuperscript{neg} program. Let \(\langle A, Q \rangle\) be an argument in \(P_1\). We can assume that (i) a strict rule \(r = H \leftarrow B\) is used in the defeasible
derivation of \( Q \) from \( \Pi \cup A \), and (ii) \( r \) is \( \text{UNFOLD}_{\text{neg}} \)-related to other rule \( r_i \) (otherwise \( \text{Args}(P_1) = \text{Args}(P_2) \), and the proposition holds trivially).

Since rule \( r \) was applied in the defeasible derivation of \( Q \) from \( \Pi \cup A \), there exists an argument \( \langle S, H \rangle \) which is a subargument of \( \langle A, Q \rangle \), such that the last rule used in the defeasible derivation of \( \langle S, H \rangle \) is \( r \). The strict rule \( r \) can be written as

\[
    r = H \leftarrow B, L_1, \ldots, L_k \quad (1)
\]

From Proposition 50, we get that \( \langle S, B \rangle, \langle S, L_1 \rangle, \ldots, \langle S, L_k \rangle \) are immediate subarguments of \( \langle S, H \rangle \).

Consider \( r_i = B \leftarrow B \), which is the last rule used in the defeasible derivation of \( \langle S, B \rangle \), such that \( r \) is \( \text{UNFOLD}_{\text{neg}} \)-related to \( r_i \). Since \( r_i \) is a strict rule, it will have the form

\[
    r_i = B \leftarrow P_1, \ldots, P_m. \quad (2)
\]

From Proposition 50, we get that \( \langle S, P_1 \rangle, \langle S, P_2 \rangle, \ldots, \langle S, P_m \rangle \) are immediate subarguments of \( \langle S, B \rangle \). Thus, argument \( \langle S, H \rangle \) in \( P_1 \) is such that \( \langle S, P_i \rangle, \ldots, \langle S, P_m \rangle \) and \( \langle S, L_1 \rangle, \ldots, \langle S, L_k \rangle \) are also arguments in \( P_1 \).

Assume we apply \( \rightarrow^*_{\text{UNFOLD}_{\text{neg}}} \) to \( P_1 \), resulting in a new DeLP_{neg} program \( P_2 \). From Definition 48, we have:

\[
    P_2 = P_1 \setminus \{ H \leftarrow B \} \cup \{ H \leftarrow ((B \setminus \{ B \}) \cup B') \mid r_i = B \leftarrow B' \in P_1 \}
\]

In this case we get \( P_2 = P_1 \setminus \{ r \} \cup \{ r' \} \), where \( r' \) is the rule

\[
    r' = H \leftarrow L_1, \ldots, L_k, P_1, \ldots, P_m \quad (3)
\]

Clearly, \( \langle S, L_i \rangle, i = 1, \ldots, k \) and \( \langle S, P_i \rangle, i = 1, \ldots, m \) are also arguments in \( P_2 \), and in particular \( \langle S, H \rangle \) is also an argument in \( P_2 \). Note that no new argument other than \( \langle S, H \rangle \) is generated in \( P_2 \), since the subarguments of \( \langle S, H \rangle \) in \( P_1 \) and \( \langle S, H \rangle \) in \( P_2 \) are the same. Thus \( \text{Args}(P_1) = \text{Args}(P_2) \).

**Corollary 52** Let \( P \) be a DeLP_{neg} program, and let \( P' \) be the program resulting from applying \( \text{UNFOLD}_{\text{neg}} \) wrt some rule \( r \) in \( P \). Then \( \text{SEM}_{\text{DeLP}}(P) = \text{SEM}_{\text{DeLP}}(P') \).
PROOF. Follows directly from Proposition 49 by repeated application of \( \rightsquigarrow \mathcal{U}_{\text{neg}} \), for each \( r_i \) which is \( \text{UNFOLD}_{\text{neg}} \)-related with \( r \).

Let us now consider tautology elimination.

**Proposition 53** Let \( \mathcal{P} \) be a \( \text{DeLP}_{\text{neg}} \) program, and \( \mathcal{P}' \) the program resulting from applying \( \text{TAUT}_{\text{neg}} \) to \( \mathcal{P} \), i.e., \( \mathcal{P} \rightsquigarrow \mathcal{P}' \) Then \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

**PROOF.** Let \( \langle \mathcal{A}, Q \rangle \) be an argument in \( \text{Args}(\mathcal{P}) \), such that \( \Pi \cup \mathcal{A} \vdash Q \) using a strict rule \( r = P \leftarrow P, Q_1, \ldots, Q_k \). Then the occurrence of \( P \) in the antecedent can also be proven from \( \Pi \setminus \{r\} \cup \mathcal{A} \). Thus, there exists a derivation for \( Q \) from \( \Pi \setminus \{r\} \cup \mathcal{A} \) (the same holds the other way around). Therefore, \( \langle \mathcal{A}, Q \rangle \in \text{Args}(\mathcal{P}) \) iff \( \langle \mathcal{A}, Q \rangle \in \text{Args}(\mathcal{P} \setminus \{r\}) \). Assume now that \( \langle \mathcal{A}, P \rangle \) is an argument in \( \text{Args}(\mathcal{P}) \), such that \( \Pi \cup \mathcal{A} \vdash P \) using a defeasible rule \( r = P \leftarrow P, S_1, \ldots, S_k \). Let \( \mathcal{A}' = \mathcal{A} \setminus \{r\} \). Clearly, \( \Pi \cup \mathcal{A}' \vdash P \). But then \( \langle \mathcal{A}, P \rangle \) is not an argument, since it is not minimal (contradiction). Therefore, no defeasible rule \( P \leftarrow P, S_1, \ldots, S_k \) can be used in building an argument. Therefore, \( \langle \mathcal{A}, P \rangle \in \text{Args}(\mathcal{P}) \) iff \( \langle \mathcal{A}, P \rangle \in \text{Args}(\mathcal{P} \setminus \{r\}) \).

It must be remarked that defeasible information in a given argument is represented through the defeasible rules used in its construction. This explains why we have to restrict ourselves to strict rules when considering \( \text{SUB}_{\text{neg}} \) and \( \text{UNFOLD}_{\text{neg}} \). Performing such transformations on defeasible rules may cause the loss of specificity information present in the antecedent of those rules (i.e., information that distinguishes a defeasible rule as 'more informed' than another). A similar situation will arise with respect to \( \text{SUB}_{\text{not}} \) and \( \text{UNFOLD}_{\text{not}} \), as presented in Section 4.2.

4.2 Transformation Properties in \( \text{DeLP}_{\text{not}} \)

\( \text{DeLP}_{\text{not}} \) is the subclass of programs in \( \text{DeLP} \) which contain only default negation \( \text{not} \), but no strict negation \( \sim \). This class can also be seen as NLP with the addition of defeasible rules. In such a setting there is no strict negation "\( \sim \)" and therefore no contradictory literals \( P \) and \( \sim P \) can appear. The attack relationship among arguments is defined in terms of default literals: an argument \( \langle \mathcal{A}, Q_1 \rangle \) accounts for a counterargument for an argument \( \langle \mathcal{B}, Q_2 \rangle \) if \( \text{not} Q_1 \) is used as an assumption in the defeasible derivation of \( Q_2 \) from \( \Pi \cup \mathcal{B} \).

Assumption literals are the only possible points for attack in \( \text{DeLP}_{\text{not}} \). In fact, we now restrict our framework in that we allow in Definition 10 only
assume \neg A \text{ where } A \text{ is an atom. That is, we do not allow } \text{assume } \neg A \text{ literals. Thus the set } \mathcal{H}(A, Q) \text{ denotes in this section the set of assumption literals in } \langle A, Q \rangle \text{ where all literals are (strictly) negated atoms. The reason is that we want to have as much assume } \neg A \text{ as is consistently possible: these negated atoms do represent the closed world assumption which is always implicit in such a setting.}

An argument involving an assumption assume \neg A \text{ will be attacked by any other argument concluding } A. \text{ In order to capture this situation, the notion of a contradictory set of literals has been extended after Definition 6 to consider assumption literals.}

Strict arguments } \langle \emptyset, R \rangle \text{ have the special property of defeating any other argument involving an assumption literal, as shown in the following proposition.}

**Proposition 54** Let } \mathcal{P} \text{ be a DeLP_not program, and let } \langle A, Q \rangle \text{ be an argument in } \mathcal{P} \text{ such that } Q \text{ follows from } A \text{ using assume } \neg R \text{ as an assumption. If } \langle \emptyset, R \rangle, \text{ then } \langle A, Q \rangle \text{ is not a justification.}

**Proof.** Clearly } \langle \emptyset, R \rangle \text{ is a counterargument for } \langle A, Q \rangle, \text{ in particular (according to specificity) a defeater. Since } \langle \emptyset, R \rangle \text{ has no defeaters (as discussed on page 12), the dialectical tree with root } \langle A, Q \rangle \text{ will have a children node } \langle \emptyset, R \rangle, \text{ which will turn out to be marked as } U \text{ (according to Definitions 27). Hence } \langle A, Q \rangle \text{ will be marked as } D, \text{ so that } \langle A, Q \rangle \text{ is not a justification.}

The precise semantics for DeLP_not depends on the analogue of Definitions 14 and 18 and the appropriate notion of a dialectical tree. Suitable definitions capture different semantics ([GSC98]). But independently of these notions, it can be stated that not Q will not hold whenever Q can be ultimately defeated. In particular, not Q will not hold whenever there is a strict argument for Q. In this respect, DeLP_not naturally extends the intended meaning of default negation in traditional logic programming (not H holds iff H fails to be finitely proven). This fact also suffices to decide which of the transformation properties are satisfied or to give counterexamples.

Since a DeLP_not program does not involve strict negation, many problems considered in Subsection 4.1 do not arise. New transformations RED^+_not, RED^-not, SUB_not, UNFOLD^r_not, UNFOLD_not and TAUT_not can be defined, with the same meaning as the ones introduced in Subsection 4.1 for DeLP$^\text{neg}$, but referring to DeLP_not programs. Similarly, we will use the } \mathcal{P} \mapsto^+_\text{not } \mathcal{P}' \text{ (resp. } \mapsto^-_{\text{not}}, \mapsto^\text{Snot}, \mapsto^\text{U_not}, \mapsto^\text{T_not}) \text{ to denote the DeLP_not program } \mathcal{P}' \text{ resulting from } \mathcal{P} \text{ by application of the transformation RED^+_not (resp. RED^-not, SUB_not, UNFOLD_not, UNFOLD^r_not, TAUT_not).}
For each transformation, we will show that the resulting transformed program is equivalent to the original one. In the case of \textsc{Sub}_{not} and \textsc{Unfold}_{not}, we restrict ourselves to strict rules, since these transformations do not hold when applied to defeasible rules (as shown in Examples 46 and 44).

**Proposition 55** Let \( \mathcal{P} \) be a \( \text{DeLP}_{not} \) program. Let \( \mathcal{P}' \) be the \( \text{DeLP}_{not} \) program resulting from \( \mathcal{P} \rightarrow_{R+not} \mathcal{P}' \). Then \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

**Proof.** Let \( \mathcal{P} \) be a \( \text{DeLP}_{not} \) program, such that \( r = P \leftarrow_{} Q_1, \ldots, \text{not} Q, \ldots, Q_k \) is a defeasible rule in \( \mathcal{P} \), and there is no rule about \( Q \) in \( \mathcal{P} \). Let \( \mathcal{P}' \) be the \( \text{DeLP}_{not} \) program resulting from applying \( \rightarrow_{R+not} \) to \( \mathcal{P} \) on rule \( r \).

Let \( H \) be an arbitrary literal in \( \mathcal{P} \), such that rule \( r \) is used in building the defeasible derivation of some argument \( \langle \mathcal{B}, S \rangle \), so that \text{assume} \( \sim Q \) is an assumption literal in \( \langle \mathcal{B}, S \rangle \). Since \( \mathcal{P}' =_{def} \mathcal{P} \setminus \{ r \} \cup \{ P \leftarrow_{} Q_1, \ldots, Q_k \} \), it is clear that \( S \) has also a defeasible derivation from \( \mathcal{B} \setminus \{ r \} \cup \{ P \leftarrow_{} Q_1, \ldots, Q_k \} \), which is minimal and non-contradictory. Hence we have the argument \( \langle \mathcal{B} \setminus \{ r \} \cup \{ P \leftarrow_{} Q_1, \ldots, Q_k \}, S \rangle \) in \( \mathcal{P}' \).

Since there is no rule with head \( Q \) in \( \mathcal{P} \), there exists no argument \( \langle \mathcal{C}, Q \rangle \) in \( \mathcal{P} \) and hence no counterargument for \( \langle \mathcal{B}, S \rangle \) at \text{assume} \( \sim Q \). Therefore each defeater for \( \langle \mathcal{B}, S \rangle \) in \( \mathcal{P} \) is also a defeater for \( \langle \mathcal{B}', S \rangle \) in \( \mathcal{P}' \), where \( \mathcal{B}' = \mathcal{B} \setminus \{ r \} \cup \{ P \leftarrow_{} Q_1, \ldots, Q_k \} \). The same line of reasoning applies if \( r \) is a strict rule \( P \leftarrow_{} Q_1, \ldots, Q_k \).

Hence each dialectical tree \( \mathcal{T} \) in \( \mathcal{P} \) involving \( \langle \mathcal{B}, S \rangle \) as a node is isomorphic to \( \mathcal{T}' \) in \( \mathcal{P}' \) involving \( \langle \mathcal{B}', S \rangle \) in \( \mathcal{P}' \). From Proposition 40 it follows that \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

**Proposition 56** Let \( \mathcal{P} \) be a \( \text{DeLP}_{not} \) program. Let \( \mathcal{P}' \) be the \( \text{DeLP}_{not} \) program resulting from \( \mathcal{P} \rightarrow_{R-not} \mathcal{P}' \). Then \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

**Proof.** Let \( \mathcal{P} = (\Pi, \Delta) \) be a \( \text{DeLP}_{not} \) program. Let \( r = P \leftarrow_{} Q_1, \ldots, \text{not} Q, \ldots, Q_n \) be a strict rule, and assume \( Q \leftarrow_{} \in \mathcal{P} \). Assume \( r \) is used in a defeasible derivation for building an argument \( \langle \mathcal{A}, H \rangle \). Clearly \( \Pi \cup \mathcal{A} \vdash Q \) and \( \Pi \cup \mathcal{A} \vdash \text{assume} \sim Q \). But this violates condition 2 in Definition 10 (contradiction). Therefore each argument \( \langle \mathcal{A}, H \rangle \) in \( \mathcal{P} \) is also an argument in \( \mathcal{P} \setminus \{ r \} \). Hence \( \text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P}') \), and therefore \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).

**Proposition 57** Let \( \mathcal{P} \) be a \( \text{DeLP}_{not} \) program. Let \( \mathcal{P}' \) be the \( \text{DeLP}_{not} \) program resulting from \( \mathcal{P} \rightarrow_{Snot} \mathcal{P}' \). Then \( \text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}') \).
PROOF. Let $\mathcal{P}$ be a $\text{DeLP}_{\text{not}}$ program, and let $r = P \leftarrow B_t$ be a non-minimal strict rule in $\mathcal{P}$ (i.e., there exists a rule $r' = P \leftarrow B_2$ such that $B_2 \subseteq B_t$). We consider $B_t = B_t^+ \cup \text{not}B_t^-$, distinguishing the set $B_t^+$ of positive literals from the set $\text{not}B_t^-$ (literals preceded by $\text{not}$). If $B_2 \subseteq B_t$, then two situations are to be considered: either $B_2^+ \subseteq B_t^+$, or $B_2^- \subseteq B_t^-$. 

(1) Suppose $B_2^+ \subseteq B_t^+$. Then $\text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P} \setminus \{r\})$, following the same line of reasoning as in Proposition 45.

(2) Suppose that $B_2^- \subseteq B_t^-$, $B_t^+ = B_t^+$. Suppose there exists an argument $\langle A, H \rangle$ such that the strict rule $r = P \leftarrow B_t$ is used in the defeasible derivation of $H$. Clearly, there is an assumption literal $\text{assume} \sim Q$ in $A$ for each $\text{not} Q$ in $B_t^-$. Let $\mathcal{H}_1$ be the set of assumption literals in $A$. It follows that $A \setminus \mathcal{H}_2$ also provides a defeasible derivation for $H$ using $r'$ instead, where $\mathcal{H}_2$ is the set of assumption literals in $r'$, such that $\mathcal{H}_2 \subseteq \mathcal{H}_1$. But then the defeasible derivation of $H$ using $r$ violates condition 3 in Definition 10. Therefore no argument using $r$ can be built in $\mathcal{P}$, so that $\text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P} \setminus \{r\})$.

From this analysis it follows that $\mathcal{P} \mapsto_{\text{S}_{\text{not}}} \mathcal{P}'$ is such that $\text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}')$.

**Proposition 58** Let $\mathcal{P}$ be a $\text{DeLP}_{\text{not}}$ program. Let $\mathcal{P}'$ be the $\text{DeLP}_{\text{not}}$ program resulting from $\mathcal{P} \mapsto_{\text{T}_{\text{not}}} \mathcal{P}'$. Then $\text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}')$.

**PROOF.** We will consider only the case in which literals preceded by $\text{not}$ are present in a rule of the form $r = P \leftarrow P, Q_1, \ldots, Q_k$. Otherwise the proof follows the same line of reasoning as in Proposition 53.

(1) Suppose there exists an argument $\langle A, H \rangle$ in $\mathcal{P}$ such that $\Pi \cup A \vdash H$ using a strict rule $r = P \leftarrow P, Q_1, \ldots, \text{not} Q, \ldots, Q_k$. Then the occurrence of $P$ in the antecedent of $r$ can also be proven from $\Pi \setminus \{r\} \cup A'$, where $A' = A \setminus \{\text{assume} \sim Q\}$. But then $\langle A, H \rangle$ is not an argument, since it violates condition 3 in Definition 10. Therefore, no rule $r = P \leftarrow P, Q_1, \ldots, \text{not} Q, \ldots, Q_k$ can be used in an argument in $\mathcal{P}$. Hence $\text{Args}(\mathcal{P}) = \text{Args}(\mathcal{P}')$, with $\mathcal{P}' = \mathcal{P} \setminus \{r\}$ so that $\text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}')$.

(2) Suppose there exists an argument $\langle A, H \rangle$ in $\mathcal{P}$ such that $\Pi \cup A \vdash H$ using a defeasible rule $r = P \leftarrow P, Q_1, \ldots, \text{not} Q, \ldots, Q_k$. The same line of reasoning as above applies, with $A' = A \setminus \{r, \text{assume} \sim Q\}$. Therefore $\text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}')$.

We present next a property of immediate subarguments in $\text{DeLP}_{\text{not}}$, similar to the one shown in Proposition 50. Then we will show that the transformation $\mapsto_{\text{U}_{\text{not}}}$ preserves semantics when applied to a given $\text{DeLP}_{\text{not}}$ program.
Proposition 59 Let \( \langle A, H \rangle \) be an argument in DeLP\(_{\text{not}}\), such that the last rule used in the derivation is the strict rule \( H \leftarrow P_1, \ldots, P_k, \text{not } L_1, \ldots, \text{not } L_j \), distinguishing literals from assumption literals. Then all immediate subarguments \( \langle A_1, P_1 \rangle, \ldots, \langle A_k, P_k \rangle \) are such that \( A_i \) = \( A \setminus \bigcup_{i=1}^{j} \{ \text{assume } \sim L_i \} \), \( \forall i = 1, \ldots, k \).

**PROOF.** Follows from the same line of reasoning in Proposition 50 when considering strict rules with assumption literals.

Proposition 60 Let \( P \) be a DeLP\(_{\text{not}}\) program. Let \( P' \) be the DeLP\(_{\text{not}}\) program resulting from \( P \mapsto U_{\text{not}} P' \) wrt a strict rule \( r \) in \( P \). Then \( \text{SEM}_{\text{DeLP}}(P) = \text{SEM}_{\text{DeLP}}(P') \).

**PROOF.** Let \( P_i = (\Pi, \Delta) \) be a DeLP\(_{\text{not}}\) program, and let \( \langle A, Q \rangle \) be an argument in \( P_i \), such that (i) a strict rule \( r = H \leftarrow B \) is used in the defeasible derivation of \( Q \) from \( \Pi \cup A \), and (ii) \( r \) is UNFOLD\(_{\text{not}}\)-related to other rule \( r_i \). If this is not the case, then clearly \( \text{Args}(P_i) = \text{Args}(P_2) \), and the proposition holds trivially. We can also assume that \( \emptyset \subset B^- \subseteq B \), i.e., there is at least one literal preceded by \text{not} in \( B \); otherwise the proposition follows directly from Proposition 51.

Since rule \( r \) was applied in the defeasible derivation of \( Q \) from \( \Pi \cup A \), there exists an argument \( \langle S, H \rangle \) which is a subargument of \( \langle A, Q \rangle \), such that the last rule used in the defeasible derivation of \( \langle S, H \rangle \) is \( r \).

The strict rule \( r \) can be written as

\[
r = H \leftarrow B, L_1, \ldots, L_k, \text{not } M_1, \ldots, \text{not } M_j
\]

(4)

distinguishing positive literals from literals preceded by \text{not}. Let \( S_i = S \setminus \bigcup_{i=1}^{j} \{ \text{assume } \sim M_i \} \). From Proposition 59, we get that \( \langle S_1, B \rangle, \langle S_1, L_1 \rangle, \ldots, \langle S_1, L_k \rangle \) are immediate subarguments of \( \langle S, H \rangle \). Hence we get that

\[
\mathcal{H}_{\langle S, H \rangle} = \mathcal{H}_{\langle S_1, B \rangle} \cup \bigcup_{i=1}^{k} \mathcal{H}_{\langle S_i, L_i \rangle} \cup \bigcup_{i=1}^{j} \{ \text{assume } \sim M_i \}
\]

(5)

Consider \( r_i = B \leftarrow B \), which is the last rule used in the defeasible derivation of \( \langle S_1, B \rangle \), such that \( r \) is \text{UNFOLD}_{\text{not}}\)-related to \( r_i \). Since \( r_i \) is an arbitrary strict rule, it will have the form

\[
r_i = B \leftarrow P_1, \ldots, P_m, \text{not } R_1, \ldots, \text{not } R_p.
\]

(6)
Let \( S_2 = S_1 \setminus \bigcup_{i=1}^{p} \{ \text{assume} \sim R_i \} \). It follows that

\[
\mathcal{H}(S_{i}, B) = \bigcup_{i=1}^{m} \mathcal{H}(S_{i}, P_i) \cup \bigcup_{j=1}^{p} \{ \text{assume} \sim R_j \} \quad (7)
\]

Replacing (7) in (5), we get

\[
\mathcal{H}(S, H) = \bigcup_{i=1}^{m} \mathcal{H}(S_{i}, P_i) \cup \bigcup_{j=1}^{p} \{ \text{assume} \sim R_j \} \cup \bigcup_{i=1}^{k} \mathcal{H}(S_{i}, L_i) \cup \bigcup_{i=1}^{j} \{ \text{assume} \sim M_i \} \quad (8)
\]

Thus, argument \( \langle S, H \rangle \) in \( \mathcal{P}_I \) is such that \( S = R_S \cup \mathcal{H}(S, H) \), where \( \mathcal{H}(S, H) \) is defined as in (8). Assume we apply \( \rightarrow_{\text{not}} \) to \( \mathcal{P}_I \), where the rule \( r \) is UNFOLD\_not-related to \( r_i \), resulting in a new \( \text{DeLP}_{\text{not}} \) program \( \mathcal{P}_2 \). From the definition of UNFOLD\_not, we have:

\[
\mathcal{P}_2 = \mathcal{P}_I \setminus \{ H \leftarrow B \} \cup \{ H \leftarrow ((B \setminus \{ B \}) \cup \mathcal{B}) \mid r_i = B \leftarrow \mathcal{B} \in \mathcal{P}_I \}
\]

Consider the original rule \( r \) in (4), and the UNFOLD\_not-related rule \( r_i \) in (6). Let \( \mathcal{P}_2 \) be the \( \text{DeLP}_{\text{not}} \) program resulting from applying the UNFOLD transformation to \( r \) with respect to \( r_i \). In this case we get

\[
H \leftarrow \{ B, L_1, \ldots, L_k, \text{not } M_1, \ldots, \text{not } M_j \} \setminus \{ B \} \cup \{ P_1, \ldots, P_m, \text{not } R_1, \ldots, \text{not } R_p \}
\]

or equivalently

\[
H \leftarrow L_1, \ldots, L_k, P_1, \ldots, P_m, \text{not } M_1, \ldots, \text{not } M_j, \text{not } R_1, \ldots, \text{not } R_p \quad (9)
\]

Let \( S' = S \setminus \{ \bigcup_{i=1}^{k} \{ \text{assume} \sim M_i \} \cup \bigcup_{i=1}^{p} \{ \text{assume} \sim R_i \} \} \). From Proposition 59, it follows that \( \langle S', L_i \rangle, i = 1, \ldots, k \) and \( \langle S', P_i \rangle, i = 1, \ldots, m \) are arguments in \( \mathcal{P}_2 \). In particular, we have

\[
\mathcal{H}(S', H) = \bigcup_{i=1}^{k} \mathcal{H}(S', L_i) \cup \bigcup_{i=1}^{m} \mathcal{H}(S', P_i) \cup \bigcup_{j=1}^{p} \{ \text{assume} \sim R_j \} \cup \bigcup_{i=1}^{j} \{ \text{assume} \sim M_i \} \quad (10)
\]

Hence \( R_S \cup \mathcal{H}(S', H) \) is an argument for \( H \) in \( \mathcal{P}_2 \), since every defeasible rule in \( \mathcal{P}_I \) is also a defeasible rule in \( \mathcal{P}_2 \). But from (8) and (10) it follows that \( \mathcal{H}(S', H) \)
\[
\begin{array}{|c|c|c|c|}
\hline
 & \text{NLP under wfs} & \text{DeLP}_{\text{neg}} & \text{DeLP}_{\text{not}} \\
\hline
\text{RED}^+ & \text{yes} & \text{no} & \text{yes} \\
\text{RED}^- & \text{yes} & \text{yes} & \text{yes} \\
\text{SUB} & \text{yes} & \text{yes, for strict rules} & \text{yes, for strict rules} \\
\text{UNFOLD} & \text{yes} & \text{yes}^a, \text{for strict rules} & \text{yes}^a, \text{for strict rules} \\
\text{TAUT} & \text{yes} & \text{yes} & \text{yes} \\
\hline
\end{array}
\]

Fig. 3. Behavior of NLP, DeLP\text{$_{\text{neg}}$} and DeLP\text{$_{\text{not}}$} under different transformations

\[^a\] Some additional conditions are required for the transformation to hold.

\[= \mathcal{H}(S, H), \text{ and the set } S' = S. \text{ Hence, } \langle S, H \rangle \text{ is an argument in both } \mathcal{P}_1 \text{ and } \mathcal{P}_2.\]

Therefore, we can conclude that for any argument \(\langle S, H \rangle\) in \(\mathcal{P}_1\) such that one of the strict rules \(r\) used in its defeasible derivation is UNFOLD\text{$_{not}$}-related to another rule \(r_i\), it follows that \(\langle S, H \rangle\) is also an argument in \(\mathcal{P}_2\). Note that no new argument other than \(\langle S, H \rangle\) is generated in \(\mathcal{P}_2\), since the subarguments of \(\langle S, H \rangle\) in \(\mathcal{P}_1\) and \(\langle S, H \rangle\) in \(\mathcal{P}_2\) are the same. Hence \(\text{Args}(\mathcal{P}_1) = \text{Args}(\mathcal{P}_2)\), and therefore \(\text{SEM}_{\text{DeLP}}(\mathcal{P}_1) = \text{SEM}_{\text{DeLP}}(\mathcal{P}_2)\).

**Corollary 61** Let \(\mathcal{P}\) be a DeLP\text{$_{\text{not}}$} program. Let \(\mathcal{P}'\) be the DeLP\text{$_{\text{not}}$} program resulting from \(\mathcal{P} \rightarrow_{U_{\text{not}}} \mathcal{P}'\) wrt a strict rule \(r\) in \(\mathcal{P}\). Then \(\text{SEM}_{\text{DeLP}}(\mathcal{P}) = \text{SEM}_{\text{DeLP}}(\mathcal{P}')\).

**Proof.** Follows directly from Proposition 49 by repeated application of \(\rightarrow_{U_{\text{not}}}^r\), for each \(r_i\) which is UNFOLD\text{$_{not}$}-related with \(r\).

### 4.3 Relating NLP and DeLP\text{$_{\text{not}}$} under WFS

A natural question is how well-founded semantics WFS relates to DeLP\text{$_{\text{not}}$}. The answer is very simple because of our results that the transformation properties are semantics preserving and the fact that programs in normalform have an obvious semantics.

**Theorem 62 (DeLP\text{$_{\text{not}}$} extends WFS)** Let \(\mathcal{P}\) be a program in NLP. We can look at \(\mathcal{P}\) also as a theory in DeLP\text{$_{\text{not}}$}. Then all atoms \(A\) and default atoms \(\text{not} A\) that are true in \(\text{WFS}(P)\) are also contained in \(\text{SEM}_{\text{DeLP}_{\text{not}}}(P)\).
**Proof.** As all the transformation properties hold, we can transform \( \mathcal{P} \) into a normal form where all rules only have negative body literals (or are empty):

- The atoms true in WFS(\( \mathcal{P} \)) are, by Theorem 36, exactly those \( A \) where there is a rule of the form “\( A \leftarrow \)”. But those atoms are certainly justified in \( \text{SEM}_{\text{DeLP}_{\text{not}}} (\mathcal{P}) \).
- All default literals \( \text{not} A \) that are true in WFS(\( \mathcal{P} \)) are, by Theorem 36, exactly those \( A \) where there is no rule with head \( A \). But then \( \text{assume} \sim A \leftarrow \) can be assumed as it can not lead to any contradiction.

**Example 63** Consider the normal logic programs

\[
\mathcal{P}_1 = \{ (a \leftarrow b), (b \leftarrow a), (c \leftarrow \text{not} a, \text{not} b) \}
\]

\[
\mathcal{P}_2 = \{ (a \leftarrow \text{not} b), (b \leftarrow a) \}
\]

\[
\mathcal{P}_3 = \{ (a \leftarrow \text{not} b), (b \leftarrow \text{not} a), (c \leftarrow a), (c \leftarrow b) \}
\]

\[
\mathcal{P}_4 = \{ (a \leftarrow b, \text{not} d), (b \leftarrow a, \text{not} d), (d \leftarrow \text{not} d), (c \leftarrow \text{not} a, \text{not} b) \}
\]

\[
\mathcal{P}_5 = \{ (a \leftarrow \text{not} b), (b \leftarrow \text{not} a), (a \leftarrow \text{not} a) \}
\]

We analyze the above NLP programs as \( \text{DeLP}_{\text{not}} \) programs.

- **WFS in \( \mathcal{P}_1 \) is \{\( \text{not} a, \text{not} b, c \). The only argument that can be constructed from \( \mathcal{P}_1 \) as a \( \text{DeLP}_{\text{not}} \) program is the one which justifies \( c \). Without the last rule \( (c \leftarrow \text{not} a, \text{not} b) \) no arguments for positive atoms can be constructed.**

- **WFS in \( \mathcal{P}_2 \) is empty. Under \( \text{DeLP}_{\text{not}} \), no argument can be built, since the only possible set \{\( \text{assume} \sim b \)\} leads to contradiction.**

- **WFS in \( \mathcal{P}_3 \) is empty. In \( \text{DeLP}_{\text{not}} \), two sets of assumptions are possible for building arguments: \( A_1 = \{\text{assume} \sim a \} \) and \( A_2 = \{\text{assume} \sim b \} \). We can build the arguments \( \langle A_1, b \rangle, \langle A_2, a \rangle, \langle A_1, c \rangle, \langle A_2, c \rangle \). Any one of these arguments has a blocking defeater. From Definition 28 it follows that no argument is justified.**

- **WFS in \( \mathcal{P}_4 \) is \{\( \text{not} a, \text{not} b, c \). The only argument that can be constructed from \( \mathcal{P}_4 \) as a \( \text{DeLP}_{\text{not}} \) program is the one which justifies \( c \). However, without the last rule \( c \leftarrow \text{not} a, \text{not} b \) no argument can be built in \( \mathcal{P}_4 \) under \( \text{DeLP}_{\text{not}} \) (there is no defeasible sequence for a nor for b).**

- **WFS in \( \mathcal{P}_5 \) is empty. But in \( \text{SEM}_{\text{DeLP}_{\text{not}}} \) the argument \{\( \text{assume} \sim b \)\} is a justification for \( a \). This is because \( \langle \{\text{assume} \sim b\}, a \rangle \) cannot be defeated (the only way to do this would be to find an argument involving the assumption \( \text{not} a \), but this would lead to a contradiction).**

The last program \( \mathcal{P}_5 \) shows that \( \text{SEM}_{\text{DeLP}_{\text{not}}} \) is strictly stronger than WFS.
Figure 3 summarizes the behavior of NLP, DeLP\textsubscript{neg} and DeLP\textsubscript{act} under the different transformation rules presented before. From that table we can identify some relevant features:

- An argumentation-based semantics has been given to NLP using an abstract argumentation framework [KT99]. From Section 4.2 it is clear that DeLP is a proper extension of NLP, since there are transformation properties in NLP which do not hold in DeLP. This is basically due to the knowledge representation capabilities provided by defeasible rules.
- Some properties of NLP under well-founded semantics are also present in DeLP (such as \texttt{TAUT} and \texttt{RED}\textsuperscript{−}). It is worth noticing that \texttt{RED}\textsuperscript{−} holds in NLP because of a “consistency constraint” (it cannot be the case that both not \textit{P} and \textit{P} hold). The same is achieved in DeLP by demanding non-contradiction when constructing arguments.
- Other transformation properties only hold for strict rules (e.g. \texttt{SUB}), sometimes with extra requirements (e.g. \texttt{UNFOLD}). This shows that defeasible rules express a link between literals that cannot be easily “simplified” in terms of a transformation rule, and a more complex analysis (e.g. computing defeat) is required.
- Some properties (e.g. \texttt{RED}\textsuperscript{+}) do not hold at all wrt. strict negation, but do hold wrt. default negation. In the first case, the reason is that negated literals are treated as new predicate names (and succeed as subgoals iff they can be proven from the program). In the second case, default negation behaves much like its counterpart in NLP. As in NLP, the absence of rules with head \textit{H} is enough for concluding that \textit{H} cannot be proven, and therefore not justified.

5 Related Work and Conclusion

5.1 Related Work

In recent work [KT99] an abstract argumentation framework has been used as a basis for defining an unifying proof theory for various argumentation semantics of logic programming. In that framework, well-founded semantics for NLP is computed by using an argument-based approach, which has many similarities with DeLP [CS99].

Many semantics for extended logic programs view default negation and symmetric negation as unrelated. To overcome this situation a semantics WFSX
for extended logic programs has been defined [ADP95]. Well-founded Semantics with Explicit Negation (WFSX) embeds a “coherence principle” providing the natural missing link between both negations: if ~L holds then not L should hold too (similarly, if L then not ~L). In DeLP this “coherence principle” also holds [GSC98].

Finally, it must be remarked the original Simari-Loui formulation [SL92] contains a fixed-point definition that characterizes all justified beliefs. A similar approach was used later by Prakken and Sartor [PS97] in an extended logic programming setting, getting a revised version of well-founded semantics as defined by Dung [Dun93]. These analogies highlight the link between well-founded semantics and skeptical argumentative frameworks.

5.2 Conclusion

We have related in this paper the logical framework DeLP to classical logic programming semantics, particularly well-founded semantics for NLP. The link between both semantics was established by looking for analogies and differences in the results of applying transformation rules on logic programs.

The differences between NLP and DeLP are to be found in the expressive power of DeLP for encoding knowledge in comparison with NLP. Defeasible rules allow the formalization of criteria for defeat among arguments which cannot be easily “compressed” by applying transformation rules, as explained in Subsection 4.4. Strict negation in DeLP is also a feature which extends the representation capabilities of NLP. However, as already discussed, the same principle which guides the application of the transformation rule RED− in NLP can be used for detecting rules that cannot be used for constructing arguments.

It is worth noting that the original motivation for DeLP was to find an argumentative formulation for defeasible theories in order to resolve potential inconsistencies. This was at the end of the 80s. In the meantime the area of semantics for logic programs underwent a solid foundational phase and today several possible semantics together with their properties are well-known. We think that these results can be applied to gain a better understanding of argumentation-based frameworks.
